President, Institute for Clinical and Economic Review

**DATE OF  
PUBLICATION:** March 23, 2015

We wish to thank all of the subject matter experts for their time participating in key informant interviews for this report. We would also like to thank Erin Lawler, Anne Loos, Matt Seidner, and Patricia Synnott of ICER for their contributions to this report.

## About ICER

The Institute for Clinical and Economic Review (ICER) is an independent non-profit research organization that evaluates medical evidence and convenes public deliberative bodies to help stakeholders interpret and apply evidence to improve patient outcomes and control costs. ICER receives funding from government grants, non-profit foundations, health plans, provider groups, and health industry manufacturers. Through all its work, ICER seeks to help create a future in which collaborative efforts to move evidence into action provide the foundation for a more effective, efficient, and just health care system. More information about ICER is available at [www.icer-review.org](http://www.icer-review.org)

## About CEPAC

The New England Comparative Effectiveness Public Advisory Council (CEPAC) is an independent, regional body of practicing physicians, methodological experts, and leaders in patient advocacy and engagement that provides objective, independent guidance on the application of medical evidence to clinical practice and payer policy decisions across New England.

Council members are elected for three-year terms, and represent a diversity of expertise and perspective; they are purposely not selected for expertise in the clinical topic under discussion in order to maintain the objectivity of the Council and to ground the conversation in the interpretation of the published evidence rather than anecdotal experience or expert opinion. Acknowledging that any judgment of evidence is strengthened by real life clinical and patient perspectives, CEPAC recruits subject matter experts for each meeting who provide input to Council members before the meeting to help clarify CEPAC's understanding of the different interventions being analyzed in the evidence review. The same clinical experts serve as a resource to the Council during their public deliberation, and help form recommendations with CEPAC on ways the evidence can be applied to policy and practice.

Led by the Institute for Clinical and Economic Review, CEPAC is supported by a broad coalition of state Medicaid leaders, integrated provider groups, public and private payers and patient representatives. For more information on CEPAC, please visit [cepac.icer-review.org](http://cepac.icer-review.org).

UHC:	United Healthcare
US:	United States
USPSTF:	United States Preventive Services Task Force
VA:	Department of Veterans Affairs
VT:	Vermont

# Executive Summary

---

## Background

This assessment evaluates the evidence on the clinical effectiveness and value of the integration of behavioral health services into primary care settings and reviews barriers and potential policy options for the implementation of such integrated care in New England.

Behavioral health integration (BHI) into primary care addresses both physical and behavioral health needs in primary care settings through systematic coordination and collaboration among health care providers. For this report, we considered behavioral health to include both mental illness and substance use disorders, and we limited our scope to conditions that are frequently diagnosed and managed in primary care settings. The report excludes efforts designed to incorporate primary care services into settings where patients are receiving specialized treatment of serious mental illness (SMI) and/or substance use disorders.

Despite a long history in the US of treating physical health conditions separately from behavioral health, the two are inextricably linked. Up to 70% of physician visits are for issues with a behavioral health component.<sup>2</sup> A similar proportion of adults with behavioral health conditions have one or more physical health issues.<sup>3</sup> Having a chronic condition is a risk factor for having a behavioral health condition and vice versa.<sup>4</sup> Depression and anxiety in particular are common in primary care settings but are often inadequately identified and treated, leading to a worsening of behavioral conditions and/or increased difficulty managing physical health conditions.

During the past two decades, many initiatives have sought to integrate behavioral health and primary care. The overall goals of BHI are those of the Triple Aim – better outcomes, better care experience, and reduced costs.<sup>20</sup> How these goals are achieved and the terms used to describe various aspects of integrated care vary extensively. Decision-makers across the health care spectrum recognize the need to better serve patients with behavioral health conditions, but questions remain regarding the latest evidence on the effectiveness and value of BHI, as well as how best to approach implementation and which aspects of integration are most important for patient success.

This assessment will support CEPAC's deliberation and attempts to answer some of the key issues related to BHI confronting patients, provider organizations, payers, and other policymakers. The goals of this report are to: 1) evaluate the evidence on the comparative clinical effectiveness and value of efforts to integrate behavioral health into primary care, 2) identify the components potentially associated with successful integration, 3) assess the potential budget impact of integrating behavioral health into primary care, and 4) provide an overview of barriers to

integration and lessons learned from national and New England-based experts to help identify potential innovations and solutions for BHI in the region. This assessment builds on a recent effort undertaken by ICER's other core program, the California Technology Assessment Forum (CTAF), but has been adapted to address the distinct challenges and opportunities for BHI in New England.

Consistent with state-of-the-art national efforts to integrate care for both mental illness and substance use disorders, most of this report provides information about both but focuses the evidence review (Section 7) on the treatment of anxiety and depression in primary care, as they are the most common behavioral health disorders treated in primary care settings.<sup>1</sup>

## Conceptual Framework

For this report, we adopted a framework published in 2013 by the Substance Abuse and Mental Health Services Administration and the Health Resources Services Administration (SAMHSA-HRSA) Center for Integrated Health Solutions (CIHS) that has six levels of collaboration/integration.<sup>26</sup> There are two levels in each of three categories (coordinated care, co-located care, and integrated care), as described below:

### Coordinated care

1. Minimal collaboration: referral network to providers at another site
2. Basic collaboration: periodic communication about shared patients

### Co-located care

3. Basic collaboration: primary care and behavioral health providers share facility but maintain separate cultures and develop separate treatment plans for patients
4. Close collaboration: providers share records and some systems integration

### Integrated care

5. Close collaboration approaching an integrated practice: providers develop and implement collaborative treatment planning for shared patients but not for other patients
6. Full collaboration in a merged integrated practice for all patients: providers develop and implement collaborative treatment planning for all patients

In this framework, collaboration refers to how resources (i.e., health care professionals) are brought together, whereas integration describes how services are delivered and practices organized and managed. Put differently, collaborative care relates to how behavioral health works with primary care, and full integrated care is when behavioral health functions within and as part of primary care.<sup>26</sup> The higher numbers for integrated care reflect the belief that they represent a greater potential for positive impact on health outcomes and patient experience.

The SAMHSA-HRSA CIHS framework emphasizes that co-location of primary care and behavioral providers does not necessarily guarantee greater collaboration or integration but that it can be beneficial. The authors of this framework note that it is not reasonable for all health care settings to move toward increasing levels of integration, and that practical considerations should drive choice of level. Other researchers have also stated that no single approach to integration will work for all communities; rather, integration should be designed for a particular set of local or statewide circumstances.<sup>2</sup>

## Existing Models for Integrated Care Delivery

Numerous approaches have been used to integrate behavioral health and primary care services in a range of settings, and several programs have emerged as models for implementing integrated services nationally. Common elements highlighted across models have been summarized extensively in the policy literature and include:

- Screening for depression, anxiety, and other behavioral disorders using validated screening tools
- Team-based care with non-physician staff to support primary care physicians (PCPs) and co-manage treatment
- Shared information systems that facilitate coordination and communication cross providers
- Standardized use of evidence-based guidelines
- Systematic review and measurement of patient outcomes using registries and patient tracking tools
- Engagement with broader community services
- Individualized, person-centered care that incorporates family members and caregivers into the treatment plan

## Effectiveness of Programs that Integrate Behavioral Health into Primary Care

For our review of the evidence on effectiveness, we focused on studies of BHI in a primary care setting with the requirement that a majority of patients have a depression and/or anxiety diagnosis. The vast majority of available studies focused on *mental health* services provided to these patients – in other words, treatment for substance use disorders as well as interventions for smoking cessation and other at-risk behaviors were not a focus of these studies.

A number of systematic reviews have assessed the effectiveness of BHI in the primary care setting among patients with depression and/or anxiety disorders. Findings from these reviews indicate that integrating mental health into primary care improves mental health outcomes such as depression and anxiety, although the effects of integration are relatively modest. Key findings from the reviews and a summary of the evidence strength for each are shown below:

### *1. Levels of Integration*

A systematic review found substantial evidence that integrated care improved mental health outcomes, but that there was no correlation between levels of integration and outcomes. Thus, our judgment is that there is insufficient evidence to assess whether higher levels or intensity of integration offer incremental benefit.

### *2. Depression*

There are a large number of randomized trials of integrated care for depression, the vast majority of which demonstrated improvements in depression outcomes with integrated care compared with usual care. Using the ICER rating,<sup>132</sup> our judgment is that there is high certainty of a small net benefit for integrated care in improving symptoms of depression compared with usual care.

### *3. Anxiety*

Only seven studies focused on anxiety, but they generally showed improvements in anxiety scores or remission. Overall, we judge there to be moderate certainty of a small net benefit for integrated care in improving symptoms of anxiety compared with usual care.

### *4. Chronic Medical Conditions*

There have been a large number of studies of the impact of integration of mental health services into primary care on diabetes outcomes. Most of the studies for other medical conditions, such as cardiovascular disease, evaluated and managed patients in the hospital or specialty clinics rather than in primary care. Diabetes is very common in primary care, and many patients with diabetes also suffer from depression. In trials, patients receiving integrated care had significantly greater decreases in hemoglobin A1c levels, depression scores, and LDL-cholesterol than patients receiving usual care. We judge there to be low certainty of a small net benefit for integrated care in improving both diabetes control and depression compared with usual care in patients with both diagnoses.

### *5. Quality of life*

Many of the randomized trials of depression reported measures of quality of life. Integrated care improved mental health quality of life more than usual care in the first 6 months, and those gains were preserved through 24 months. The trend still favored integrated care beyond 24 months, but it was no longer statistically significant. There were no early improvements in physical health quality of life, but the differences became significant between 13 and 24 months. We judge there to be high certainty of a small to moderate net benefit for integrated care in improving quality of life in the mental health domain compared with usual care. There is low certainty of a small net benefit for integrated care in improving quality of life in the physical health domain compared with usual care.

## 6. *Patient satisfaction*

Patients in randomized trials were significantly more satisfied with integrated care. The size of the benefit was modest but highly statistically significant. We judge there to be high certainty of a small to moderate net benefit for integrated care in improving patient satisfaction compared with usual care.

In sum, there is a very large body of literature on the integration of mental health into primary care. Studies of different models of integration across widely varying delivery systems demonstrate with great consistency that integrated care improves depression and anxiety outcomes, although the absolute benefits are only small to modest. Furthermore, integrated care improves patient quality of life and satisfaction with care. There is inadequate evidence to assess whether greater integration would lead to larger improvements in outcomes.

## **Components of BHI Associated with Treatment Success**

Research on the impact of individual components of BHI on depression-related or other health outcomes is extremely limited. To complement previous research analyzing factors of collaborative care associated with improvement in depressive symptoms and use of anti-depression medication, we conducted an analysis of the factors of integrated care most frequently reported in studies with successful outcomes.

We identified 36 models of integrated care that reported statistically significant improvements in one or more primary outcomes of interest, such as sustained improvement in depression or anxiety symptoms, likelihood of receipt of antidepressant therapy, and medication adherence. The most common program component across successful models was inclusion of a standardized care coordination plan that involved regular interaction with both patient and physician (86%), followed by formal patient education at 69%. Both supervision of care coordinators and systematic screening in primary care were included in two-thirds of successful models, while inclusion of a standardized schedule of psychotherapy appeared in approximately half. The addition of new dedicated staff, presence of formalized stepped care plans, and use of shared medical records were the least common program components. Only two models included all eight components.

## **Comparative Value of BHI**

ICER has adopted the following framework for assessing the comparative value of health care interventions, with value assessed according to two distinct constructs:

- *Care Value:*
  1. Comparative clinical effectiveness of each intervention vs. alternatives (considering both clinical benefits and harm)
  2. Any additional “non-clinical” benefits (e.g., reduced caregiver burden)
  3. Contextual considerations (no other acceptable treatment, vulnerable populations)
  4. Cost-effectiveness (incremental cost to achieve important patient outcomes vs. alternatives)
  
- *Health System Value:*
  1. Care value of the intervention of interest (as above) AND
  2. Potential effects of short-term budgetary impact from the intervention on other patients in the health care system

Our economic analysis had three components:

1. To assess comparative care value, we conducted a detailed analysis of the available literature on the economic impact of BHI in primary care for the treatment of depression and/or anxiety with a focus on the differential impact of BHI in certain subgroups of patients, key drivers of economic impact, and any trends in comparative value over time.
2. We also describe publicly-available resources for planning and implementing BHI as well as estimating start-up, implementation, and incremental “steady state” costs associated with BHI.
3. We estimated the per-member, per-month (PMPM) budgetary impact of implementing BHI in an individual accountable care organization (ACO) based on assumed levels of implementation costs and ongoing “steady-state” costs over one year.

Our consideration of care value is based on a relatively robust evidence base for both clinical effectiveness and cost-effectiveness of BHI interventions for depression and anxiety in primary care. Available studies have been relatively consistent in showing incremental clinical benefit over usual care, at least in terms of mental health outcomes. In addition, while not explicitly measured in these studies, there does not appear to be any potential harm to the patient from integration efforts. Finally, while the quality of available economic evaluations could be greatly improved, findings from multiple evaluations across a variety of integration models and populations suggest that BHI falls within generally-acceptable thresholds for cost-effectiveness (\$15,000 - \$80,000 per quality-adjusted life year gained vs. usual care).

Assessment of health system value is much more complex, however, as the investment in BHI and the potential for return on investment varies greatly depending on the realities faced in any individual setting. Economic studies have shown with consistency that BHI increases organizational costs, at least in the short term. Our own budgetary impact analysis suggests that first-year expenses for a 200,000 member ACO are sizeable, even in a relatively low-risk population. The

incremental PMPM expense of BHI (\$2.74) generated in this analysis represents an 11% increase over a cited primary care benchmark PMPM of \$26.<sup>200</sup>

Evidence on longer-term cost savings is more limited, focused on specific subpopulations (e.g., patients co-diagnosed with diabetes) in many instances, and subject to methodological concerns in others (e.g., incomplete accounting of start-up or practice-wide costs, tracking of health care costs at periods distal to end of intervention). In addition, while there are not currently consistent data with which to estimate potential cost offsets from BHI, fairly conservative estimates of reductions in health care costs could offset these initial investments considerably.

## **Barriers and Potential Opportunities**

ICER staff conducted semi-structured interviews with regional and national subject matter experts and reviewed the policy literature to understand real world perspectives on practice and delivery system innovations, barriers to change, and opportunities for improving how behavioral health care services are integrated into primary care. Interviewees came from each New England state and represented academic institutions, patient advocacy organizations, state agencies, primary care practices, and health plans. A full description of the various perspectives represented is available in the full report.

Despite the desire of many to integrate behavioral health into primary care, significant barriers have been articulated by researchers and practitioners across the US.<sup>35,202,204,205</sup> We identified several areas in our discussions with key informants and review of the policy literature where improvements may be made to support BHI. Barriers and the potential opportunities to overcome them can be grouped into the following categories and are described in Table ES.1 on the following page:

- Cultural and historical influences
- Licensing and certification
- Technology, information sharing, and performance measurement
- Provider training and practice capacity
- Clinical operations, workflow and spacing
- Reimbursement and payment policies

**Table ES.1 Summary of Barriers to and Opportunities for BHI in New England**

Category	Specific Issues
Cultural and Historical Influences	<p><b>Barriers</b></p> <ul style="list-style-type: none"> <li>• Separate silos for behavioral health and physical health – both in terms of service delivery and financing</li> <li>• Distinct practice cultures between primary and specialty behavioral health care that are reinforced by differences in training, licensing, and certification for primary care, mental health, and substance use</li> <li>• Ongoing societal stigma related to mental health and substance use conditions</li> </ul>
	<p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Support from senior leadership to gain consensus and advance BHI beyond beginning stages</li> <li>• Tailored job descriptions to attract candidates with the vision and skill set required for BHI</li> </ul>
Licensing and Certification	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Requirements that practices acquire separate licenses from multiple government agencies or departments to co-locate services</li> <li>• Legislation that poses barriers to co-location, such as requirements that practices have separate waiting rooms for behavioral health and primary care patients</li> </ul>
	<p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Licensure amendments that make access to BHI (through contract or direct service) a requirement for licensure</li> </ul>
Technology/ Information sharing	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Challenges related to limited data sharing via electronic health records (EHRs), which are preferred but are not as widely used by behavioral health providers as by physical health providers</li> <li>• Interoperability of different EHR systems and the inability to customize health record templates to meet unique practice needs as well as manage and monitor behavioral health input</li> <li>• Confidentiality laws that are more restrictive for behavioral health (particularly for substance use) than for physical health</li> <li>• Fragmented communication among providers of primary care, mental health, and substance use services</li> </ul>
	<p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Use of community health workers (CHWs) or patient navigators to identify when patients receive specialty mental health services and help support coordination of services between primary care and specialty behavioral health providers</li> <li>• EHR systems that embed communication tools and directly link to data registries to monitor patient outcomes</li> </ul>

Category	Specific Issues
Provider training and capacity	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Limited training of primary care physicians in behavioral health conditions and of behavioral health providers in physical health conditions</li> <li>• Shortage of primary care and behavioral health providers to meet the needs of the communities they serve, as well as substantial variation in provider supply across the region</li> <li>• Scope of practice concerns, particularly in primary care where resources and time are already limited</li> <li>• Lack of access to specialty behavioral health providers for patients with severe behavioral health needs, which places additional strains on BHI in primary care</li> </ul> <p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Specialized integrated care training that helps primary care staff and practice leadership for the unique BHI environment</li> <li>• Development of consultation “hubs” that allow primary care providers serving patients with behavioral health conditions to connect with call centers staffed by behavioral health specialists to provide guidance and clinical advice in real time</li> <li>• Development of central databases and clearinghouses of providers accepting new patients to help individuals access behavioral health services</li> <li>• Use of telemedicine to link patients in areas with staffing shortages to providers in other areas</li> </ul>
Clinical operations, workflow, and space	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Challenges related to adapting clinical workflows and scheduling to accommodate greater levels of flexibility and real-time collaboration</li> <li>• Lack of space to place physical and behavioral health team members on same floor or same building</li> </ul> <p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Population-based strategies that screen all patients for depression and anxiety using validated screening tools and protocols that triage patients with positive screens to appropriate levels of care</li> <li>• Adoption of flexible scheduling approaches that reserve blocks of time for provider-to-provider consultation or use of open-access booking that reduces the number of no-shows for visits</li> <li>• Fully embedding behaviorists on the care team by hiring full-time staff that are included in all team meetings and co-manage treatment plans with other primary care team members</li> </ul>

Category	Specific Issues
Reimbursement and payment	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Payment that has historically rewarded volume through fee-for-service payments rather than outcomes through capitated payments and shared risk/shared savings models</li> <li>• Limitations on billing including: <ul style="list-style-type: none"> <li>○ Who can bill for services</li> <li>○ Requirements that services be delivered face-to-face to be eligible for payment</li> <li>○ Lower reimbursement for health and behavioral assessment/intervention (HBAI) codes typically used by non-physician providers than for evaluation and management (E&amp;M) codes typically used by physicians</li> <li>○ Inability to bill for care coordination and communication activities</li> </ul> </li> <li>• Challenges related to establishing global payment rates that are cost-saving but provide an appropriate level of revenue to practices</li> <li>• Challenges related to adapting existing delivery and payment models such as ACOs and PCMHs to support BHI</li> <li>• Lack of consensus around outcome measures for BHI and how performance should be evaluated to support reimbursement efforts tied to performance</li> </ul> <p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Use of alternative payment models such as capitation, and/or financial incentives to integrate care such as shared savings and/or shared risk; capitation payments should be risk-adjusted</li> <li>• Enhanced capitation payments for care management services and collaborative care delivered in integrated care settings</li> <li>• Reimbursement for psychiatry consults to primary care by phone</li> <li>• Use of performance incentives to reward clinical improvement and have withholds for inappropriate care</li> <li>• Allowance for same-day billing of physical and mental health services when provided by two separate providers</li> <li>• Increased reimbursement of evidence-based practices</li> <li>• Increased payment for non-physician providers</li> <li>• Reduced restrictions on types of providers who can bill for certain services</li> </ul>

At the public CEPAC meeting on May 1, 2015, these barriers and potential solutions will be discussed at length with the Council and a Policy Roundtable composed of subject matter experts. CEPAC will also cast votes to assess the comparative effectiveness and value of BHI (draft questions for deliberation are posted for public comment on the CEPAC [website](#)). Following the public meeting, this section will be updated to summarize the discussion of CEPAC members and Policy Roundtable participants regarding the evidence and will include a formal set of policy recommendations related to implementing BHI.

# Introduction

---

This assessment for the New England Comparative Effectiveness Public Advisory Council (CEPAC) evaluates the evidence on the clinical effectiveness and value of the integration of behavioral health services into primary care settings and reviews barriers and potential policy options for the implementation of such integrated care in New England.

## Scope of Review

Behavioral health integration (BHI) into primary care addresses both physical and behavioral health needs in primary care settings through systematic coordination and collaboration among health care providers. For this report, we considered behavioral health to include both mental illness and substance use disorders, and we limited our scope to conditions that are frequently diagnosed and managed in primary care settings.

Consistent with state-of-the-art national efforts to integrate care for both mental illness and substance use disorders, most of this report provides information about both but focuses the evidence review (Section 7) on the treatment of anxiety and depression in primary care, as they are the most common behavioral health disorders treated in primary care settings.<sup>1</sup> Studies that include patients with serious mental illness (SMI) or substance use disorders are included as long as >50% of the population studied was diagnosed with depression and/or anxiety; otherwise they are excluded. This is designed to focus the assessment on studies that involve management and triage of patients presenting in the primary care setting and to exclude studies focusing on the delivery of primary care services in settings where patients are receiving specialized treatment for SMI and/or substance use disorders.

## Context

Despite a long history in the US of treating physical health conditions separately from behavioral health conditions, the two are inextricably linked. Up to 70% of physician visits are for issues with a behavioral health component.<sup>2</sup> A similar proportion of adults with behavioral health conditions have one or more physical health issues.<sup>3</sup> Having a chronic condition is a risk factor for having a behavioral health condition and vice versa.<sup>4</sup> Depression and anxiety in particular are common in primary care settings but are often inadequately identified and treated, leading to a worsening of behavioral health conditions and/or increased difficulty managing physical health conditions.

The economic impact of behavioral health conditions is also significant. Care for patients with comorbid behavioral health conditions can cost 2-3 times more than care for patients without these comorbidities,<sup>5</sup> and these individuals can have substantially shorter life expectancies than the

average person.<sup>3</sup> Additional national health care expenditures related to behavioral health comorbidities were estimated to be \$293 billion in 2012, with approximately 217 million days of work lost annually at a cost of \$17 billion/year.<sup>5</sup> Behavioral health spending is concentrated among public insurers. Medicaid beneficiaries are twice as likely to have mental illness, and Medicaid finances more than 25 percent of behavioral health spending in the US.<sup>6,7</sup>

During the past two decades, many initiatives have sought to integrate behavioral health and primary care. Decision-makers across the health care spectrum recognize the need to better serve patients with behavioral health conditions, but questions remain regarding the latest evidence on the effectiveness and value of BHI as well as how best to approach implementation and which aspects of integration are most important for patient success. This report focuses on the integration of behavioral health into primary care. Such integration is designed to improve screening and/or treatment in primary care settings through systematic coordination and collaboration among health care providers to address both physical health and behavioral health needs. Simply stated, it involves whole-person care and “reconnecting the head to the body.”

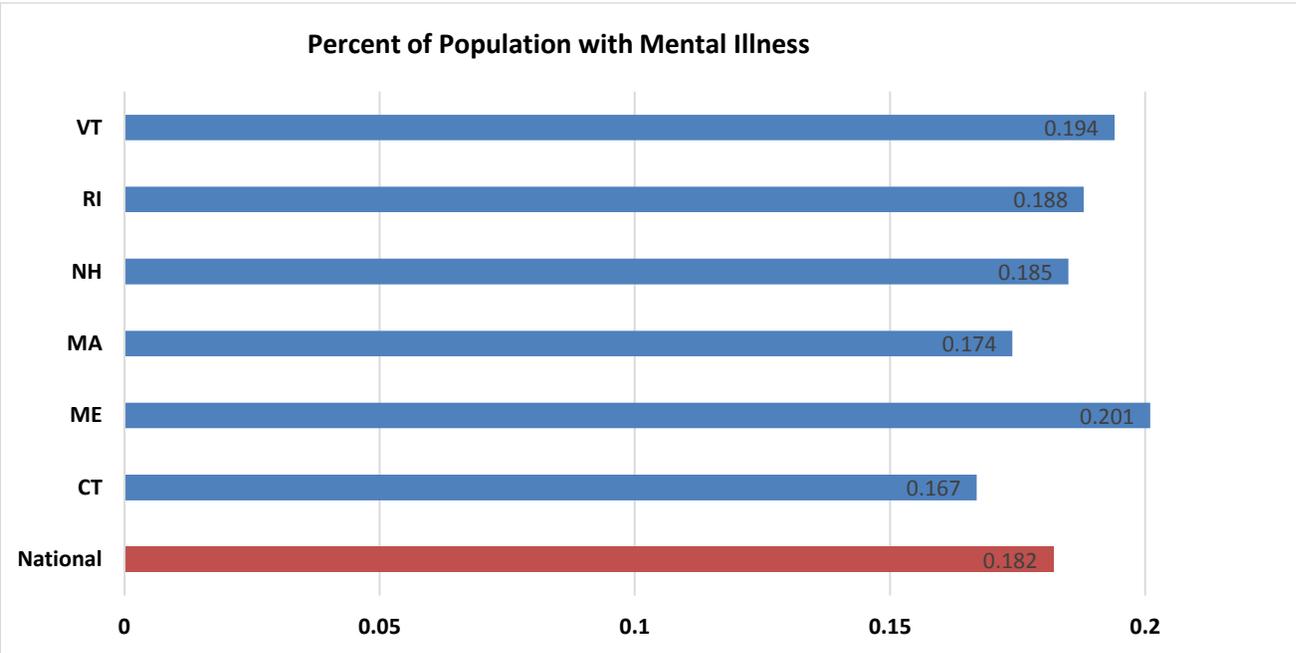

This assessment will support CEPAC’s deliberation and attempts to answer some of the key issues confronting patients, provider organizations, payers, and other policymakers. The goals of this report are to: 1) evaluate the evidence on the comparative clinical effectiveness and value of efforts to integrate behavioral health into primary care, 2) identify the components potentially associated with successful integration, 3) assess the potential budget impact of integrating behavioral health into primary care, and 4) provide an overview of barriers to integration and lessons learned from national and New England-based experts to help identify potential innovations and solutions for BHI in the region. This assessment builds on a recent effort undertaken by ICER’s other core program, the California Technology Assessment Forum (CTAF), but has been adapted to address the distinct challenges and opportunities for BHI in New England.

# 1. Background

## 1.1 Behavioral Health Conditions

Behavioral health conditions are common; more than one quarter of the US population is reported to have a mental health and/or substance use disorder in any given year.<sup>8</sup> In the US, about 44 million adults have a mental disorder,<sup>9</sup> and about 10 million of those have a SMI that substantially interferes with or limits major life activities.<sup>10</sup> In New England, rates of behavioral health disorders are similar – nearly one of every five adults in the region has a mental health need (see Figure 1 below).<sup>11</sup>

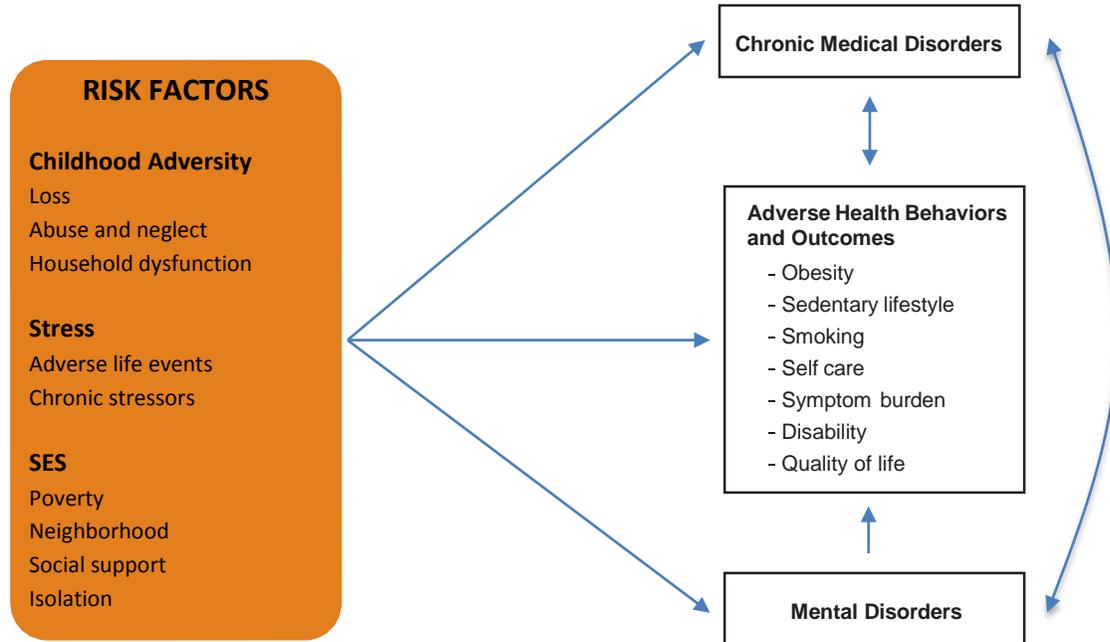

**Figure 1: Prevalence of Mental, Behavioral, and Emotional Disorders among Adults, National and New England**

Source: [Substance Abuse and Mental Health Services Administration. The 2011 and 2012 National Survey on Drug Use and Health](#), February 2014.<sup>11</sup>

While lifetime prevalence is higher, about 7% of adults reported having a major depressive episode (lasting at least two weeks) in the past 12 months, and more than 18% had an anxiety disorder.<sup>12,13</sup> Many patients have both mental health conditions and medical conditions: 29% of the adult population with medical conditions also have mental disorders, and 68% of the adult population with mental disorders also have medical conditions.<sup>14</sup> As shown in Figure 2 on the next page, a variety of risk factors affect both medical and mental disorders, and there are inter-relationships between chronic medical disorders, adverse health behaviors and outcomes, and mental disorders.

**Figure 2. Model of Interaction between Mental and Medical Disorders**

Source: Druss BG, Walker ER. Mental disorders and medical comorbidity, RWJF Research Synthesis Report 21, Feb. 2011.<sup>3</sup>

In sum, the population to be served by integrated care is complex, with many individuals having co-occurring mental health and substance use disorders along with chronic physical health conditions, being homeless or in transitional housing, and experiencing other socioeconomic determinants of poor health (e.g., limited job opportunities and transportation, poverty, exposure to crime/violence).

Although behavioral health services represent a relatively small portion of total health spending in the US (6.3% in 2009),<sup>15</sup> they have a large impact on public budgets. Government agencies purchase nearly 60% of mental health services in the US, with Medicaid representing 28% of total expenditures, other state and local government 18%, Medicare 8%, and other federal sources 5%.<sup>16</sup> Compared to other regions of the country, states in New England spend more per resident on behavioral health and allocate a larger share of total health spending to behavioral health services. In 2005, the most recent year for which data is available, New England states spent 9% of total health spending on behavioral health services and \$866 per resident (2014 dollars), compared to the national average of \$567.<sup>17</sup>

Most diagnoses of behavioral health conditions, especially depression and anxiety, are made in the primary care setting. Despite the high prevalence of these conditions, more than half of those who have a behavioral health condition are not treated for it.<sup>18,19</sup> Multiple factors contribute to this,

including lack of extensive training in behavioral health among primary care providers, relatively short appointment times to address a patient’s multiple needs, limitations on access to behavioral health specialists, and restrictions on billing for services.

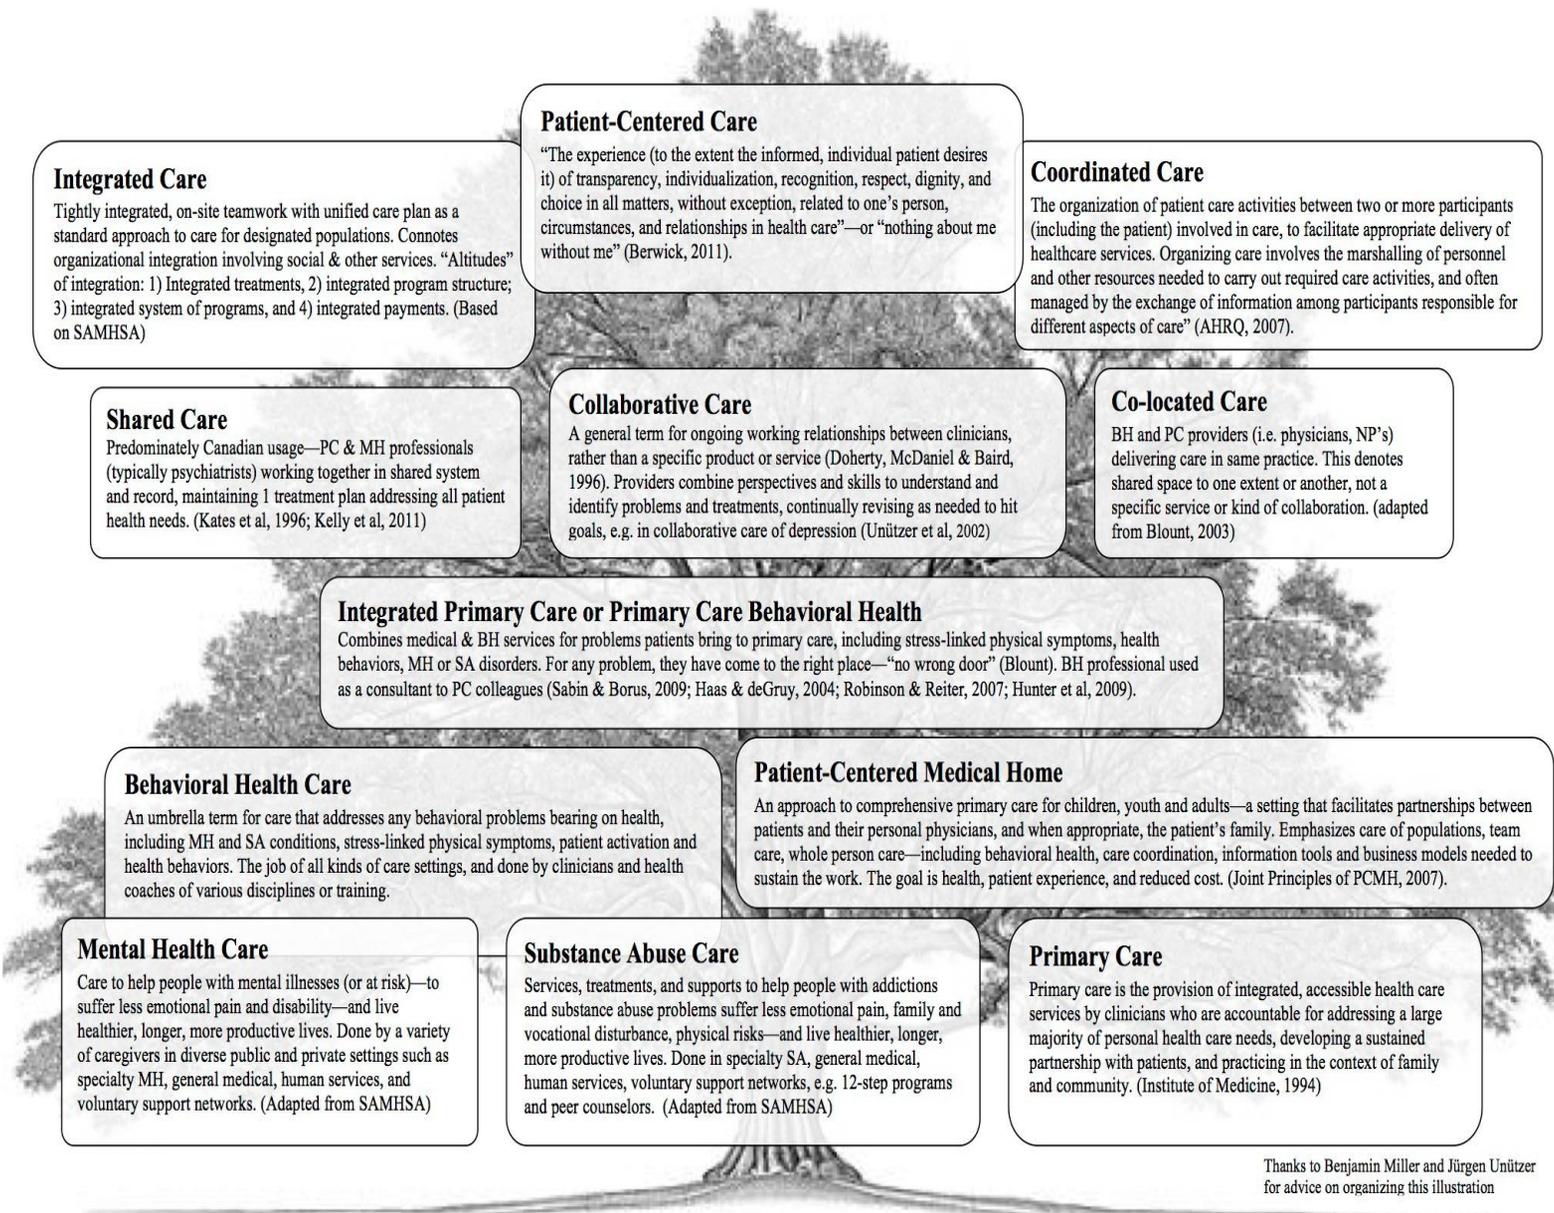

## **1.2 Conceptual Framework**

The overall goals of BHI are those of the Triple Aim – better outcomes, better care experience, and reduced costs.<sup>20</sup> How these goals are achieved, and the terms used to describe various aspects of integrated care, vary extensively and include “co-located care,” “collaborative care,” “integrated primary care,” “care management,” and “patient-centered care,” among others (see Figure 3 on the next page).<sup>21</sup> Federal agencies including the Agency for Healthcare Research and Quality (AHRQ), the Substance Abuse and Mental Health Services Administration (SAMHSA), and the Health Resources Services Administration (HRSA) have provided thought leadership on the topic of integrating behavioral health into primary care. Contributions from these federal agencies are described below.

### **AHRQ Lexicon and Integration Framework**

AHRQ created an *Academy for Integrating Behavioral Health and Primary Care* that is designed to be both a “coordinating center and a national resource for people committed to delivering comprehensive, integrated health care.”<sup>22</sup> Recognizing the need for a standardized vocabulary in this emerging field, the Academy supported development of a consensus *Lexicon*, which is a set of concepts and definitions designed to enable effective communication among various stakeholders discussing and implementing integration.<sup>23</sup> The Lexicon is intended to be a functional definition and describe actual practice; this is in contrast to previous definitions in the field that “emphasized values, principles, and goals.”<sup>23</sup>

**Figure 3. Family Tree of Terms in Use in the Field of Collaborative Care**

Source: Peek CJ and the National Integration Academy Council. Lexicon for Behavioral Health and Primary Care Integration. AHRQ Publication No. 13-IP001-EF. 2013<sup>23</sup>

Building on the Lexicon, while noting the need for a more specific set of observable and measurable functions within integrated care, the Academy also developed an *Integration Framework* that specifies functional domains and/or actions and measurement constructs for integrated behavioral health care.<sup>24</sup> Functional domains refer to high-level functions or actions such as care team expertise, clinical workflow, and data collection and use. Measurement constructs describe specific characteristics (i.e., structures), actions (i.e., processes), and outcomes for each of the functional domains. The framework appears to be useful for organizations interested in the elements of each function that are important for design, implementation, and measurement of success within a given organization, but are less well-suited to a critical assessment of the level of integration across organizations. In the following section, we describe another integration framework that is more easily applied to the programs described in the accumulated body of evidence for this topic.

### SAMHSA-HRSA CIHS Levels of Collaboration/Integration

Building on the five-level collaboration continuum initially specified by Doherty (1995)<sup>25</sup> and other subsequent work, the SAMHSA-HRSA Center for Integrated Health Solutions (CIHS) published a framework in 2013 that has six levels of collaboration/integration.<sup>26</sup> Because it is the current framework produced and disseminated by the federal agency focused on substance abuse and mental health services, is commonly used by practitioners, and is more suitable to the summary of evidence we provide in this report, we adopted this framework (described briefly below) as an organizing tool in the evidence review (Section 7).

There are two levels in each of three categories (coordinated care, co-located care, and integrated care), as described below:

#### Coordinated care

1. Minimal collaboration: referral network to providers at another site
2. Basic collaboration: periodic communication about shared patients

#### Co-located care

3. Basic collaboration: primary care and behavioral health providers share facility but maintain separate cultures and develop separate treatment plans for patients
4. Close collaboration: providers share records and some systems integration

#### Integrated care

5. Close collaboration approaching an integrated practice: providers develop and implement collaborative treatment planning for shared patients but not for other patients
6. Full collaboration in a merged integrated practice for all patients: providers develop and implement collaborative treatment planning for all patients

In this framework, collaboration refers to how resources (i.e., health care professionals) are brought together, whereas integration describes how services are delivered and practices organized and managed. Put differently, collaborative care relates to how behavioral health works with primary care, and full integrated care is when behavioral health functions within and as part of primary care.<sup>26</sup> The higher numbers for integrated care reflect the belief that they represent a greater potential for positive impact on health outcomes and patient experience.

### Integration Considerations

The SAMHSA-HRSA CIHS framework emphasizes that co-location of primary care and behavioral providers does not necessarily guarantee greater collaboration or integration but that it can be beneficial (e.g., may reduce travel time for patients, may increase likelihood that patient makes and keeps an appointment with a behavioral health provider, may increase communication between physical and behavioral health providers). The authors of this framework note that it is not reasonable for all health care settings to move toward increasing levels of integration and that practical considerations should drive choice of level.

In a review of integrated care models, Collins et al (2010) suggest that integration should be designed for a particular set of local or statewide circumstances, taking into account such factors as the population being targeted, provider availability/training, service capacity in the community, consumer preferences, funding/reimbursement, and regulatory restrictions.<sup>2</sup> They note that there is no single approach that will work for all communities, and that differences in needs, resources, and practice patterns will influence which model is the best fit for a specific community. The practice model adopted may range from loose collaboration across separate providers where case managers are used to coordinate services with complex needs to a fully collaborative system of care where behavioral health and primary care services are woven seamlessly together.

## **1.3 Workforce Considerations**

Intrinsic to BHI is team-based care and collaboration across different types of providers. Depending on the practice setting and unique population needs, AHRQ identified the following categories of potential members of integrated care teams:<sup>27</sup>

- Primary care providers, including physicians, physician assistants (PAs), nurse practitioners (NPs)
- Behavioral health providers, such as clinical social workers (LCSWs), psychiatrists, psychologists, counselors, marriage and family therapists (MFTs)
- Allied health professionals, such as health educators, community health workers (CHWs), pharmacists, care coordinators, peer specialists, patient navigators

The practice change required to integrate behavioral and physical health services typically involves scope-of-practice changes and retraining of staff to meet program objectives. Academic training rarely includes formal education on effective collaboration and how to work with other members of a care team.<sup>28</sup> For example, psychologists are rarely oriented to the unique culture and needs of primary care as part of standard training,<sup>29</sup> and primary care physicians often lack exposure to management of behavioral health conditions in their training programs. Moreover, most integration strategies involve the addition of a care manager role, or someone whose job it is to coordinate services and support for the patient and among providers. Care managers can come from a range of disciplines, including nursing, social work, or psychology, and typically require training explicit to the role.

Two federally sponsored initiatives support training efforts and the development of a standard set of core competencies needed for integrated care settings. AHRQ is conducting an observational study of successfully integrated primary care sites to develop a set of workforce competencies to help guide training for behavioral health and primary care providers. In 2014, the SAMHSA-HRSA CIHS also developed a set of core competencies to help inform workforce training and orientation, recruitment, and performance assessment.<sup>30</sup> Split across 10 major domains, SAMHSA-HRSA CIHS' competencies apply to both physical and behavioral health practitioners and prioritize effective communication and teamwork, knowledge of evidence-based behavioral health interventions and screening strategies, and cultural competence. The full set of competencies are summarized in Table 1 below.

**Table 1. Summary of SAMHSA-HRSA CIHS Core Competencies**

Category	Competencies
<b>Interpersonal Communication</b>	<p>The ability to establish rapport quickly and to communicate effectively with consumers of health care, their family members, and other providers.</p> <p>Examples include: active listening; conveying information in a jargon-free, non-judgmental manner; using terminology common to the setting in which care is delivered; and adapting to the preferred mode of communication of the consumers and families served.</p>
<b>Collaboration and Teamwork</b>	<p>The ability to function effectively as a member of an interprofessional team that includes behavioral health and primary care providers, consumers, and family members.</p> <p>Examples include: understanding and valuing the roles and responsibilities of other team members, expressing professional opinions and resolving differences of opinion quickly, providing and seeking consultation, and fostering shared decision-making.</p>

Category	Competencies
<b>Screening and Assessment</b>	<p>The ability to conduct brief, evidence-based, and developmentally appropriate screening and to conduct or arrange for more detailed assessments when indicated.</p> <p>Examples include screening and assessment for: risky, harmful or dependent use of substances; cognitive impairment; mental health problems; behaviors that compromise health; harm to self or others; and abuse, neglect, and domestic violence.</p>
<b>Care Planning and Coordination</b>	<p>The ability to create and implement integrated care plans, ensuring access to an array of linked services, and the exchange of information among consumers, family members, and providers.</p> <p>Examples include: assisting in the development of care plans, whole health, and wellness recovery plans; matching the type and intensity of services to consumers' needs; providing patient navigation services; and implementing disease management programs.</p>
<b>Intervention</b>	<p>The ability to provide a range of brief, focused prevention, treatment, and recovery services, as well as longer-term treatment and support for consumers with persistent illnesses.</p> <p>Examples include: motivational interventions, health promotion and wellness services, health education, crisis intervention, brief treatments for mental health and substance use problems, and medication assisted treatments.</p>
<b>Cultural Competence and Adaptation</b>	<p>The ability to provide services that are relevant to the culture of the consumer and their family.</p> <p>Examples include: identifying and addressing disparities in health care access and quality, adapting services to language preferences and cultural norms, and promoting diversity among the providers working in interprofessional teams.</p>
<b>Systems Oriented Practice</b>	<p>The ability to function effectively within the organizational and financial structures of the local system of health care.</p> <p>Examples include: understanding and educating consumers about health care benefits, navigating utilization management processes, and adjusting the delivery of care to emerging health care reforms.</p>
<b>Practice-Based Learning and Quality Improvement</b>	<p>The ability to assess and continually improve the services delivered as an individual provider and as an interprofessional team.</p> <p>Examples include: identifying and implementing evidence-based practices, assessing treatment fidelity, measuring consumer satisfaction and health care outcomes, recognizing and rapidly addressing errors in care, and collaborating with other team members on service improvement.</p>
<b>Informatics</b>	<p>The ability to use information technology to support and improve integrated health care.</p> <p>Examples include: using electronic health records (EHRs) efficiently and effectively; employing computer and web-based screening, assessment, and intervention tools; utilizing telehealth applications; and safeguarding privacy and confidentiality.</p>

Reproduced from [SAMHSA-HRSA Center for Integrated Health Solutions](#), 2014<sup>30</sup>

Training programs to develop a workforce for integrated care have proliferated in recent years, with nearly 100 integrated care training programs now available across the US.<sup>31</sup> Efforts to develop the workforce for integrated care are especially salient given the projected shortage of primary care physicians (PCPs) and behavioral health professionals.<sup>32,33</sup> A more comprehensive discussion of the workforce issues related to BHI is in Section 9.

## 2. Contextual Issues: Regulations and Policies Affecting BHI

---

Integration of behavioral health care requires substantial effort given the long history of separate financing, different types of service providers with different expectations about treatment, and real or perceived barriers to sharing data across providers. This section provides an overview of the regulatory, financial, and administrative context affecting how behavioral health and primary care services are integrated. A summary table capturing the key similarities and differences in the regulatory and financial environment for BHI across New England states is available on page 22. A detailed discussion of practice and delivery system innovations, barriers, and opportunities for BHI in New England is in Section 9. It is important to recognize that the landscape for BHI is constantly evolving and that this section should therefore be considered a “snapshot” of the status at the time of the report’s publication.

### 2.1 Administrative Oversight, Billing, and Information Sharing

#### Regulatory Oversight and Financing

Physical and behavioral health services have historically been regulated and financed through multiple tiers of government and separate agencies, leading to the fragmented delivery of care. It is not uncommon for decisions affecting the provision and financing of physical health, mental health, and substance use services to be split across multiple entities, complicating the ease with which care can be integrated at the practice level. For instance, in many states all practices must seek licensing and credentialing through multiple governmental departments, such as Medicaid, mental health, and alcohol/drug agencies, in order to co-locate and be reimbursed for services; this is complicated by each entity often having different budgets, processes, and regulations.<sup>35</sup> Moreover, the separate entities charged with regulating health services may have unique responsibilities and goals that can be at odds with one another, making it difficult in some states to form a cohesive strategy for BHI. The division of responsibilities for physical and behavioral health may also exacerbate the cultural divide between services at the practice level by creating distinct sources of support and guidance that fail to bridge the two areas of care.<sup>34</sup>

In most New England states, the administrative and financial responsibility for physical and behavioral health services are split across multiple government agencies or departments. It is not uncommon in the region for behavioral health purchasing, rate setting, and contracting on behalf of public beneficiaries to come under the purview of Medicaid, but for behavioral health licensing, the provision of specialty behavioral health services, and some portion of behavioral health purchasing

to be delegated to a separate entity. Even though nearly all states in New England consolidate administrative oversight for behavioral and physical health services within one umbrella agency, decision-making and regulatory authority is typically still split across multiple departments and programs.

### Medicaid Billing

Complex billing rules also pose a significant challenge to BHI. Even though a standard set of Current Procedural Terminology (CPT) and diagnostic codes are maintained nationally, each state Medicaid program has unique billing rules that affect how behavioral health services are reimbursed. Many Medicaid programs place restrictions on same-day services, meaning that providers within the same organization are unable to bill for behavioral and physical health visits on the same day, and/or a single practitioner cannot receive reimbursement for providing both types of service on the same day unless specifically licensed to do so.<sup>35</sup>

Medicaid additionally limits the specific procedures and diagnoses for which primary care providers can receive reimbursement. Further, in-person consultation is a common requirement for billing, even though the coordination that is core to integrated care is often performed outside of the patient visit.<sup>35</sup> Existing codes may not comprehensively address the full scope of integrated care, meaning that some activities central to integration, like communication and consultation across providers, are not reimbursable. To address some of these concerns, the Centers for Medicare & Medicaid Services (CMS) added six Health and Behavior Assessment and Intervention (HBAI) service codes in 2010 to better support integrated services and allow for the billing for services related to behavioral, social, psychological and cognitive issues that impact the management of physical health problems. Medicaid programs may also place limitations on the type of practitioner that can bill and receive payments for behavioral health services, often excluding “nontraditional” health care professionals such as peer support specialists and CHWs that are increasingly relied on in integrated settings.<sup>34</sup> A summary of Medicaid billing rules and other health insurer reimbursement policies specific to New England is available in Section 5.

Medicaid programs, as well as commercial health plans, are pursuing alternative payment methodologies that allow for greater flexibility in how behavioral health services are reimbursed in primary care settings, but fee-for-service (FFS) payments, which do not provide incentives for integrated care, remain pervasive. Further discussion of potential options and solutions to reimbursement is in Section 9.

### Information Sharing: Confidentiality and Electronic Health Records (EHRs)

Federal and state privacy laws intended to protect patient confidentiality have important implications for the integration of care. The Health Insurance Portability and Accountability Act

(HIPAA) regulates the disclosure and use of patient health information. It contains broad exceptions that allow for data disclosure without prior consent from the patient when related to treatment, payment, and operational activities.<sup>a,36</sup> More stringent criteria exist for facilities providing treatment for substance use disorders, which affects the ability of practitioners in these centers to share data with primary care practices. States may also employ stricter requirements in addition to HIPAA that can further limit practitioners from sharing information and facilitating coordinated services. This is the case in Vermont, where clinicians must obtain explicit permission from a patient before any health information acquired while attending a patient can be disclosed.<sup>214</sup>

Some states in the region have separate protections that apply only to the disclosure of mental health information. Rhode Island requires patient consent for mental health information to be shared with practitioners outside of the facility where the patient receives treatment.<sup>37</sup> In Connecticut and Massachusetts, state legislation requires all records from psychologists to be confidential, and they cannot be shared except in very limited circumstances unless written consent is provided by the patient.<sup>38</sup> Vermont has broader protections, and requires all information pertaining to a patient's mental illness or developmental disability to be kept confidential.<sup>214</sup> Table B in the Appendix provides an overview of key state legislation impacting the disclosure of patient medical information across care teams.

The enactment of HIPAA and other patient protection laws has coincided with the spread of electronic health records (EHRs) in the US.<sup>39</sup> EHR adoption has become a national policy priority to better facilitate coordination across providers and allow individual practitioners to access patient health information expediently to inform treatment decisions.<sup>40</sup> However, in part due to more stringent privacy laws affecting the care of patients with substance use and mental illness disorders, behavioral health organizations have adopted EHR systems at a much slower pace than have other health care settings.<sup>40</sup> Moreover, recent incentive programs that reward practices with higher payments from Medicare and Medicaid for adopting EHR systems exclude many behavioral health providers, including psychologists and social workers.<sup>41</sup> Federal efforts have been made to support infrastructure that allows for the exchange of health information between physical health and behavioral health providers, but these initiatives are primarily in the form of individual pilot projects, and the lack of widespread use of EHRs among behavioral health professionals and practices remains an issue.<sup>42</sup>

---

<sup>a</sup> Psychotherapy notes have special rules under HIPAA legislation. Patients must provide written prior authorization consent for their disclosure or use by a practitioner, but this only applies when the notes are separate from the patient's individual medical record.

## **2.2 Purchasing Arrangements for Behavioral Health Services**

### **Behavioral Health Carve-Outs**

Public and private health plans often “carve out” some or all behavioral health services from their benefit package to be managed by a separate organization. Delegating the financial and administrative responsibility for behavioral health to organizations with specific expertise in this area was historically intended to ensure appropriate use of behavioral health services but can also hinder the integration of care. In a carve-out model, the provision and financing of a patient’s physical and behavioral health care are coordinated across multiple organizations, each with potentially distinct provider networks, budgets, and policies. In these circumstances, the responsibility for enrolling practitioners, defining covered benefits, setting reimbursement rates, and collecting and reporting data for behavioral health services is delegated to a separate organization.<sup>43</sup> For clinicians, carve-outs may mean that physical and behavioral health services are reimbursed through different payment models, thereby misaligning incentives. In some cases, carve-out networks are limited to mental health specialists, meaning that primary care provider groups are unable to directly participate on carve-out panels.<sup>34</sup> Carve-outs can also make it difficult to access comprehensive patient information across entities, additionally hindering integration at the provider level. For these reasons, as the importance of integrating behavioral and physical care has become more recognized, state Medicaid programs as well as commercial payers are increasingly pursuing strategies that align financial accountability and coordination across organizations, or are shifting towards integrated arrangements that manage the administration and purchasing of both behavioral and physical health services.

## **2.3. Payment and Care Delivery Initiatives**

### **Accountable Care Organizations (ACOs)**

National health reform through the Affordable Care Act (ACA) has created opportunities for clinical integration by supporting the development of alternative payment models that provide incentives for clinicians to coordinate services and provide quality care more efficiently. Accountable Care Organizations (ACOs), or networks of health care providers that share clinical and financial responsibility for a defined patient population,<sup>44</sup> may be particularly well-suited to integrate behavioral and physical health services due to unique incentives that emphasize primary care and foster greater coordination across providers. Unlike with traditional FFS payment structures, ACOs receive payments for controlling costs and meeting certain quality benchmarks and have more flexibility to provide services such as care management that are not typically reimbursed.<sup>45</sup>

However, a recent survey of ACOs from across the country revealed that BHI is still limited in these settings, in part because of contract arrangements that continue to carve out behavioral health services and costs from the rest of primary care.<sup>46</sup>

New England has experienced significant ACO activity relative to the rest of the country. Maine, Massachusetts, Rhode Island, New Hampshire, and Vermont are among eight states in the US estimated to have more than 10 percent of their populations covered by ACOs.<sup>47</sup>

### Medical Homes and Health Homes

The patient-centered medical home (PCMH) is another model that has evolved to improve the quality and efficiency of primary care delivery. Also referred to as a primary care medical home, many of the core principles of PCMHs overlap with the goals of integration, including physician-led team-based care, coordinated services across disciplines, and person-centered services that comprehensively address the physical, psychosocial, and behavioral aspects of treatment. PCMHs differ in how they are reimbursed, but many have adopted a payment structure that combines FFS with supplemental per-member per-month (PMPM) payments to cover the cost of coordinated care, as well as opportunities for bonuses based on performance in key outcomes.<sup>48</sup> The National Committee for Quality Assurance (NCQA) launched its PCMH Recognition program in 2008 to develop standards and guidelines for practices working to transform how primary care is organized. The most recent set of standards issued in 2014 placed an expanded focus on BHI, including new requirements for team-based care, depression screening, and care management for patients with behavioral disorders. Standards with aspects specific to BHI are provided in Table 2 on the next page.

Several states in the region have robust PCMH programs, including Connecticut's Husky Health PCMH initiative<sup>49</sup> and Maine's Quality Counts program, each involving over 70 practices.<sup>50</sup> Rhode Island's Care Transformation Collaborative is one of the oldest multi-payer PCMH pilots in the US and has grown to serve over 300,000 individuals statewide and has recently begun to integrate behavioral health services into an increasing number of its PCMH practices.<sup>51</sup> Vermont's Blueprint for Health runs over 100 PCMH practice locations,<sup>52</sup> and Massachusetts launched a PCMH Initiative that oversees over 50 practices.<sup>53</sup> From 2008-2011, New Hampshire ran a multi-payer PCMH pilot, though does not currently have an active statewide PCMH program.<sup>54</sup>

The ACA recently expanded on the medical home model to explicitly address the coordination of physical and behavioral health services. Health Homes, established in section 2703 of the ACA, are designated practice organizations (typically safety net providers, including federally qualified health centers (FQHCs) and community mental health facilities) that use health care teams to provide comprehensive case management, coordination, individual and family support, community referrals, and transitional care services to populations with multiple chronic conditions, including

behavioral health disorders.<sup>55</sup> Whereas PCMHs have involved multiple payer participation, Health Homes are currently exclusive to Medicaid. Health Homes are also reimbursed using alternative payment methodologies, typically PMPM capitated rates. Only a small number of states have established Health Homes to date, with more currently receiving planning grants to implement the model. Maine, Rhode Island, and Vermont are the only states in New England with approved Health Home amendments,<sup>83</sup> though Rhode Island’s and Vermont’s efforts focus only on patients with SMI and substance use disorders, respectively.<sup>56, 57</sup> Connecticut is also pursuing a Behavioral Health Home but will also focus on patients with SMI.<sup>58</sup>

**Table 2. Summary of 2014 NCQA PCMH Standards Specific to BHI**

Standard	Description
<b>Team-Based Care</b>	<ul style="list-style-type: none"> <li>Practices document and communicate to patients how behavioral health needs will be addressed</li> <li>Members of the care team are trained and assigned to support patients/families/caregivers in self-management, self-efficacy, and behavior change</li> </ul>
<b>Population Health Management</b>	<ul style="list-style-type: none"> <li>Tobacco use status is captured in an electronic record of all patients aged 13 and older</li> <li>Clinicians perform comprehensive health assessments that include 1) attention to an individual’s health behaviors, 2) history and family history of behavioral health conditions, and 3) an understanding of social and cultural factors that affect health</li> <li>Clinicians screen for depression using a standardized tool in practices with access to relevant services when results are positive</li> <li>Clinical decision support is implemented using evidence-based guidelines for behavioral health disorders and conditions related to unhealthy behaviors</li> </ul>
<b>Care Management Support</b>	<ul style="list-style-type: none"> <li>Clinicians use a systematic process to identify patients for clinical care management using criteria that prioritizes populations with a high prevalence of behavioral health disorders</li> </ul>
<b>Care Coordination and Transitions</b>	<ul style="list-style-type: none"> <li>Practices maintain agreements with behavioral health providers to enhance access, communication, and coordination</li> <li>Leadership describes the integration approach to behavioral health providers within the practice site</li> </ul>

### State Innovation Models (SIM) Initiatives

The State Innovation Models (SIM) Initiative is a program of the Center for Medicare & Medicaid Innovation (CMMI) that provides federal grants to states to test multi-payer health care delivery and payment reform models for improving care quality while reducing costs. Many award recipients are using SIM funding to develop an enhanced primary care delivery system that is responsive to the comprehensive needs of patients and integrates care across sectors.<sup>60</sup> Each state in New

England has received either a Model Testing grant (funding to test their innovation plan) or a Model Design award (funding to support further planning and development of an innovation plan).<sup>60</sup> Efforts in the region have overlapped with the goals of integration and have typically focused on expanding existing ACO and PCMH programs, investing in EHR infrastructure, supporting workforce development and training for team-based care, and using alternative payment models to support BHI and other integrated care efforts. A summary of the different approaches New England states are adopting as part of the SIM initiative to develop primary care and foster BHI are described in Table 3 below.

**Table 3. Summary of BHI Efforts in New England SIM Models**

State	Award Type	Primary Care Delivery System Features	Select Efforts related to BHI in primary care <sup>b</sup>
CT <sup>61</sup>	\$45M Model Test Award	PCMHs	<ul style="list-style-type: none"> <li>• Expand certified PCMHs and develop CT-specific PCMH criteria related to BHI</li> <li>• Offer awards and technical assistance to health systems and FQHCs to develop clinical care teams and integrate behavioral health</li> <li>• Develop inter-professional training curricula to prepare future primary care professionals for team-based care</li> <li>• Introduce shared savings contracts to Medicaid to promote greater accountability for quality and costs in this population and flexibility to provide integrated services</li> <li>• Expand EHR infrastructure to support communication across care providers</li> </ul>
ME <sup>62</sup>	\$33M Model Test Award	PCMHs ACOs	<ul style="list-style-type: none"> <li>• Expand number of PCMHs utilizing team-based care approaches to support chronically ill patients</li> <li>• Development of workforce models that provide care management to high-risk high-utilizing patients with chronic illness and peer support for high risk populations</li> <li>• Support training efforts for primary care clinicians serving patients with behavioral health needs</li> <li>• Expand alternative payment models like shared savings and global capitation that provide greater flexibility for BHI</li> <li>• Implement EHRs in behavioral health settings to support care coordination and integration with primary care</li> </ul>

<sup>b</sup> Some states in New England have developed programs as part of SIM initiatives to integrate primary care services into specialty mental health settings or Behavioral Health Homes serving patients with SMI, as in Rhode Island and Maine. These programs are not discussed here as the focus of the report is integrating behavioral health into primary care settings.

<b>MA<sup>62</sup></b>	\$44M Model Test Award	PCMHs ACOs	<ul style="list-style-type: none"> <li>• Provide support for primary care practices transitioning to PCMH models</li> <li>• Develop alternative primary care payment methodologies that incorporate shared savings/shared risk models with added quality incentives based on statewide metrics</li> <li>• Support public and private payers in transitioning to the model</li> <li>• Enhance data infrastructure to provide better accountability and care coordination</li> </ul>
<b>NH<sup>63</sup></b>	\$1.6M Model Design Award		<ul style="list-style-type: none"> <li>• Improve access for individuals at risk of requiring long-term supports and services (LTSS) through Medicaid</li> <li>• Implement practices that empower the patient in coordination of care</li> <li>• Better coordinate services provided through medical, behavioral, and LTSS systems</li> <li>• Develop an incentive program that shares savings with providers if system-wide improvements are achieved<sup>64</sup></li> </ul>
<b>RI<sup>87</sup></b>	\$20M Model Test Award	PCMHs Health homes ACOs	<ul style="list-style-type: none"> <li>• Develop a Population Health Plan based on a baseline assessment of community health, including the integration of behavioral health and primary care</li> <li>• Expand and strengthen existing network of PCMHs, Health Homes, and ACOs through a Transformation Network that will provide technical assistance and analytical support to providers and payers adopting value-based approaches</li> <li>• Support the development of community health teams to strengthen linkages between primary care and community resources</li> <li>• Expand state's health information technology infrastructure to support uptake of EHRs</li> <li>• Facilitate the statewide implementation of tools to support substance abuse prevention and early treatment</li> <li>• Explore alternative payment models, including pay-for-performance (P4P) and shared savings</li> </ul>
<b>VT<sup>62</sup></b>	\$45M Model Test Award	PCMHs ACOs	<ul style="list-style-type: none"> <li>• Create a model that increases coordination between primary care and specialists</li> <li>• Develop three alternative payment models: <ul style="list-style-type: none"> <li>• An ACO model that integrates payment and delivery across the entire system through a shared-savings payment model</li> <li>• A bundled payment model that integrates payment and services across independent providers</li> <li>• A P4P model that improves the quality, performance, and efficiency of providers</li> </ul> </li> <li>• Improve telemedicine and home-monitoring services <ul style="list-style-type: none"> <li>• Defined strategies and mechanisms for moving to a more value-based, patient-centered system</li> </ul> </li> </ul>

**Medicaid and Health Center Expansion**

The expansion of Medicaid programs authorized by the ACA may bring greater significance to integration efforts, as individuals gaining coverage through Medicaid are disproportionately

affected by behavioral disorders. The ACA also established new requirements that health insurance sold through Health Insurance Marketplaces or provided by Medicaid to newly eligible adults must cover mental health and substance use services to the same extent as all other covered medical benefits.<sup>66</sup> The ACA expands on existing legislation through the Mental Health Parity and Addiction Act of 2008 that requires group health plans and insurers with existing coverage for behavioral health conditions to provide coverage that is comparable to that of medical and surgical care.<sup>67</sup> Five out of six New England states adopted Medicaid expansion, adding over 600,000 additional enrollees to regional Medicaid programs since 2013.<sup>68-73</sup>

The ACA also established an \$11 billion trust fund to finance the expansion of FQHCs to address the behavioral and primary care needs of the patients they serve. FQHCs have a long history of providing comprehensive health care to underserved populations, and in many states have been at the center of innovative efforts to integrate behavioral health services. A 2010 national survey of FQHCs indicated that 65 percent provided some level of integrated services.<sup>74</sup> Federal investment in FQHCs is intended to increase the capacity for community health centers to provide comprehensive, integrated primary health care services, particularly in environments with expanded access to health care coverage.<sup>75</sup>

## Telemedicine

Telemedicine, or the use of electronic information and telecommunication technology to provide health at a distance, has emerged in recent years as a tool to support integrated care. In areas where populations are dispersed and/or there are insufficient human and capital resources to provide behavioral health services in primary care settings, practices have turned to telemedicine to link patients with physical and behavioral health providers under one system of care. Telemedicine has been used to provide general health assessment, psychotherapy, medication management, and psychiatric diagnostic assessment, though the type of services reimbursed using telemedicine varies significantly across payers.<sup>76</sup> There is a national trend for states to require telemedicine services to be reimbursed at the same rate as in-person visits by private insurers.<sup>77</sup> Medicare and Medicaid programs also typically provide some degree of coverage for telemedicine, though each state has unique requirements that affect the setting in which services can be provided, as well the type of providers who can deliver services.<sup>78</sup> Access to telemedicine is also affected by state licensing rules that require practitioners to be licensed in the state where the patient is receiving care.<sup>79</sup>

In New England, regulatory and clinical standards for telemedicine typically do not differ from those of in-person practice. All states in the region require out-of-state physicians providing telemedicine to become fully licensed in the state where the patient resides, though many state boards offer a more streamlined path to licensure for physicians coming from states that have equivalent licensing standards.<sup>80</sup> New England states allow physicians to consult with out-of-state clinicians regarding a patient's care through telemedicine, though states generally require such physician-to-physician

consultation to be performed on an ad hoc or temporary basis before additional licensing is required. Most states in the region require private health insurers to reimburse some level of telemedicine, though at present Connecticut, Maine, and Vermont are the only states in which telemedicine is reimbursed by Medicaid.<sup>c,82</sup> Table 4 below provides an overview of regulatory standards for telemedicine in each New England state.

**Table 4. Summary of Regulations and Standards for Telemedicine in New England**

Regulation/Standard	CT	ME	MA	NH	RI	VT
<b>Allows out-of-state physicians providing telemedicine to practice without license in state where patient resides?</b> <sup>81</sup>	No	No	No	No	No	No
<b>Allows for provider-to-provider consultation from out-of-state physicians?</b> <sup>220</sup>	Yes – time limits apply	Yes – time limits apply	No	Yes	Yes – time limits apply	Yes
<b>Private insurance coverage for telemedicine required?</b> <sup>77</sup>	No	Yes	Yes	Yes	No	Yes
<b>Medicaid reimbursement for telemedicine?</b> <sup>82</sup>	Yes	Yes	No	No	No	Yes

<sup>c</sup> Connecticut passed legislation in 2012 that allowed for Medicaid to reimburse telemedicine services, but only on a limited basis through pilot demonstration projects.

## Summary

The sections above provide an overview of the administrative, regulatory, and financial context affecting the capacity of each state in the region to pursue BHI. The policy environment for BHI is influenced by a number of factors, including: 1) the organizational structure of how healthcare services are regulated and financed, 2) Medicaid billing rules, 3) patient confidentiality protections that may inhibit information-sharing across providers, 4) the utilization of carve-out arrangements to manage behavioral health care, 5) growth in the Medicaid population, 6) number of FQHCs and alternative payment and delivery system models that provide greater flexibility to support BHI, 7) the availability of SIM funding to advance primary care, 8) whether the state is developing Medicaid Health Homes to coordinate care for chronically ill patients, and 9) the availability of telemedicine. Each of these factors contribute to the unique barriers and potential solutions for integrating behavioral health into primary care in New England that are discussed in Section 9. Table 5 on the following page provides an overview of the unique context for BHI in each state in the region. The factors mentioned are constantly evolving and are not intended to provide a comprehensive list of all potential influences on BHI.

**Table 5. Contextual Considerations for BHI in New England**

	CT	ME	MA	NH	RI	VT

<sup>d</sup> Estimates are based on comparison of CMS January 2015 data to July-September 2013 average enrollment data, the period before the initial open enrollment period of the Health Insurance Marketplaces.

<sup>e</sup> New Hampshire Medicaid expansion will take effect in August 2015. New Hampshire has received a federal waiver to provide low-income adults with federal premium assistance to purchase health insurance through private health plans.

## 3. Existing Models for Integrated Care Delivery

---

Numerous approaches have been used to integrate behavioral health and primary care services in a range of settings. The evidence review in Section 7 explores the comparative effectiveness of different levels of integration and seeks to identify the key program components that correspond to patient success. Several advanced programs have emerged that have served as models for implementing integrated services nationally and regionally, each with distinctive features and core similarities to how care is organized and coordinated. Common elements highlighted across models have been summarized extensively in the policy literature and include:

- Screening for depression, anxiety, and other behavioral disorders using validated screening tools
- Team-based care with non-physician staff to support PCPs and co-manage treatment
- Shared information systems that facilitate coordination and communication cross providers
- Standardized use of evidence-based guidelines
- Systematic review and measurement of patient outcomes using registries and patient tracking tools
- Engagement with broader community services
- Individualized, person-centered care that incorporates family members and caregivers into the treatment plan

Selected models are briefly described below to provide context to how integration is being approached in primary care. A table with a more comprehensive description of each program is provided in Appendix A. We chose to highlight these systems of BHI as they are among the most developed programs and have served as models for integrating behavioral health into primary care in a variety of settings.

### 3.1 Summary of Select Models for BHI

#### National Models

##### *Cherokee Health Systems (Behavioral Health Consultants)<sup>88</sup>*

Cherokee Health Systems is a network of FQHCs and community mental health organizations in Tennessee that operates over 50 clinic sites throughout the state. This system takes a population-based approach to care management whereby every patient is screened for behavioral health conditions and triaged to the appropriate level of support. Generalist Behavioral Health Consultants (BHCs) are fully embedded on the care team and work collaboratively with PCPs to develop treatment plans and co-manage patient care. BHCs are available to provide rapid access to behavioral services – often during the same patient visit – and are a standard feature of well-child

visits and prenatal appointments. Psychiatric consults are available to provide guidance and support for more complex cases. Team members are connected through a system of EHRs and use standard measures to track patient outcomes.

#### *Department of Veterans Affairs (VA)<sup>89</sup>*

The VA integration program built on a strong existing infrastructure to implement a national strategy for BHI that focuses exclusively on SMI and depression. The program involves several individual projects that are coordinated but are individualized to each site's unique needs. Under this system, PCPs provide universal screening of depression and post-traumatic stress disorder (PTSD). Patients with positive screens are assessed for behavioral health needs using structured protocols performed by care managers. Depression care managers are included on the primary care team and make recommendations to the PCP about treatment, provide proactive patient follow-up, and communicate with consultant psychiatric specialists when problems arise. EHRs are used to facilitate provider communication, report data, and provide point-of-care decision support.

#### *IMPACT Model/Collaborative Care<sup>90</sup>*

Developed by the University of Washington, the IMPACT/Collaborative Care model integrates treatment for a range of mood and anxiety disorders into primary care settings. The Advancing Integrated Mental Health Solutions (AIMS) Center based at the University of Washington focuses on the implementation of Collaborative Care and has worked with hundreds of practices nationally and internationally to apply and adapt the model. Under this system, patients are screened for depression and anxiety using validated screening tools. Care managers are core members of the care team and work with PCPs to support medication management and to provide brief counseling and other services as well as coordinate across providers. Psychiatric consults are available to support PCPs when diagnosing patients and making treatment adjustments. Patient progress is systematically tracked and monitored using a central data registry.

#### *Intermountain Healthcare Mental Health Integration Program<sup>91</sup>*

Intermountain Healthcare is an integrated health system of over 20 hospitals and 200 outpatient clinics serving the metropolitan area of Salt Lake City, Utah. The health system built on existing institutional structures for coordinated care to integrate primary care and behavioral health services. Features of this model are being applied to health systems nationally, including in Maine, Mississippi, New Hampshire, and Oregon. At Intermountain, all patients receive a comprehensive mental health assessment and are screened for depression, anxiety, and other behavioral health concerns using validated screening tools. PCPs and other behavioral health team members collaborate to develop shared treatment plans and provide for seamless patient transition across providers. A secure, central health information exchange is available to all team members to track and upload patient data, using a standard set of measures.

## Regional Models

In New England, a variety of approaches to BHI are being pursued. The following programs serve as examples for how BHI is being approached in different settings in the region.

### *Maine Health<sup>92,93</sup>*

MaineHealth is an integrated health system providing services in Central and Southern Maine. MaineHealth's Behavioral Health Integration program was developed based on the model put forth by Intermountain Healthcare (see previous page) and has been applied in over 30 primary care practices in both rural and urban settings. In these practices, patients receive care from a team of providers, including a primary care physician, clinical staff, and a care manager. Behavioral health providers are available onsite in every practice to provide consultations and other services at the request of the primary care provider. Currently, about 60% of all patients are screened for depression using standardized tools. MaineHealth providers use a shared EHR to allow for easy transfer of information between all members of the care team, including behavioral health providers.

### *Dartmouth Hitchcock-Keene<sup>94,95</sup>*

Dartmouth Hitchcock-Keene (DH-K) provides primary care services to over 65,000 patients in New Hampshire. All sites are NCQA level 3 PCMHs that include integrated behavioral health care. Team-based care is a central component of DH-K's practices, with providers at each site divided into teams that include a primary care physician, a behavioral health specialist, and other health professionals. Teams participate in regular group meetings, or "huddles," to discuss cases and collaborate on decisions regarding patient care. Providers use a shared EHR system that includes both medical information and mental health information. All patients in DH-K's practices are screened for depression and anxiety using validated, standardized screening tools.

### *New Haven "WrapAround" model<sup>216</sup>*

The Clifford W. Beers Guidance Clinic, Inc. recently received close to \$10M from CMMI to deliver an integrated model of care across a network of practices in New Haven, including FQHCs, a pediatric hospital, and school clinics. The program will target high-needs Medicaid families and use a "WrapAround" team composed of care coordinators, CHWs, behavioral health providers, PCPs, nutritionists, school nurses and psychologists, psychiatrists, and other community resources to screen, assess, and triage patients to needed levels of service. Care teams will establish family-focused care plans and coordinate services to address a family's unique physical and behavioral health needs. Care will be integrated across multiple health care and community settings to reduce the fragmentation of services.

## *Vermont Blueprint for Health*<sup>96,97</sup>

The Vermont Blueprint for Health is a statewide initiative that involves practices, hospitals, health centers, and other stakeholders in implementing a statewide service model. This is a multi-payer initiative that has involved both public and private insurers. A key goal of the Blueprint is to transform primary care practices throughout the state into PCMH practices that incorporate behavioral health services. To assist practices in their transformation, the state has developed an in-depth facilitation program known as the Expansion and Quality Program (EQuIP). Through EQuIP, participating practices receive support from trained program facilitators to help build the PCMH, as well as to help with implementation of an EHR. Practices receive fee-for-service payments as well as a PMPM rate.

Vermont Blueprint also supports the creation of Community Health Teams that provide support services in the PCMH settings once the practices have achieved NCQA recognition. Teams are led by RNs and may also include mental health specialists, nurse care coordinators, social workers, CHWs, and other professionals as determined by the specific needs of each PCMH's patient population. Each Community Health Team includes five full-time employees, and the associated costs are shared between Vermont's Medicaid program and commercial insurers.

## 4. Clinical Guidelines and Policy Statements

---

### Guidance for Integrating Behavioral Health in Primary Care Settings

Joint Principles for Integrating Behavioral Health into the Patient-Centered Medical Home (PCMH), 2014

[http://www.aafp.org/dam/AAFP/documents/practice\\_management/pcmh/initiatives/PCMHJoint2014Update.pdf](http://www.aafp.org/dam/AAFP/documents/practice_management/pcmh/initiatives/PCMHJoint2014Update.pdf)

A joint statement from multiple clinical societies promotes the use of PCMHs for integrating care. Each patient in a PCMH should have a personal physician who is primarily responsible for the patient's care but will also have access to a team of health care professionals including a behavioral health specialist, who should ideally be co-located to improve access and coordination. Information technology should include information from all providers on the care team, including the behavioral health provider's patient notes, mental health screening and case finding tools, and outcome tracking.

Funding should be pooled between physical and behavioral health providers using a model such as PMPM capitation payments. Payment should be available for behavioral health services provided in a face-to-face setting, as well as telemedicine services (e.g., telephone, electronic communications). Services associated with the coordination of care should be available to all patients including services provided by separate team members on the same day.

American Association of Community Psychiatrists (AACP), 2002

[http://www.communitypsychiatry.org/pages.aspx?PageName=AACP\\_Position\\_Paper\\_on\\_Interface\\_and\\_Integration\\_with\\_Primary\\_Care\\_Providers](http://www.communitypsychiatry.org/pages.aspx?PageName=AACP_Position_Paper_on_Interface_and_Integration_with_Primary_Care_Providers)

The American Association of Community Psychiatrists (AACP) suggests that mental health professionals working in community-based settings should become more familiar with the culture of primary care. AACP outlines several key characteristics of an integrated model including behavioral health triage, capacity for ongoing behavioral health consultation support and training for PCPs and staff, and care monitoring with chronic disease management protocols.

AACP recommends integrated settings be staffed with master's degree or higher-level mental health professionals, as well as mental health professionals with prescribing privileges, and nurse staff or other non-mental health trained staff to provide some or all of care monitoring and support services. AACP supports implementation of ongoing measures to evaluate program success, including accuracy of diagnosis of psychiatric disorders for patients seen in primary care, the effectiveness and cost-effectiveness of services provided, clinical outcome indicators, and satisfaction of both patients and providers.

Department of Veterans Affairs (VA), 2008

[http://www.mirecc.va.gov/VISN16/docs/UMHS\\_Handbook\\_1160.pdf](http://www.mirecc.va.gov/VISN16/docs/UMHS_Handbook_1160.pdf)

The VA Uniform Mental Health Services Handbook establishes minimum requirements for VA Mental Health Services. Included in the numerous regulations outlined in the Handbook is an overarching requirement that systems provide integration or coordination between care for mental health conditions and other aspects of health care for all veterans. Patients must have a principal mental health provider while receiving mental health care. All veterans receiving mental health care must be enrolled in a VA primary care clinic for their primary care needs. If veterans are not already enrolled in VA primary care, their mental health providers must assist them in receiving all appropriate screenings and preventive interventions in the mental health clinic. Mental health programs are not intended to function as isolated entities but rather within the larger context of the VA system.

United States Preventive Services Task Force (USPSTF), 2009

<http://www.uspreventiveservicestaskforce.org/Page/Document/RecommendationStatementFinal/depression-in-adults-screening>

The USPSTF supports screening for depression in primary care to assure accurate diagnosis, effective treatment, and follow-up. The guidelines mention several tools for primary care providers to use to diagnose depression, and note that shorter, informal screening tests that include questions about loss of interest in activities or depressed mood may be just as effective as a more formal assessment.

Institute for Clinical and Systems Improvement (ICSI), 2013

[https://www.icsi.org/guidelines\\_more/catalog\\_guidelines\\_and\\_more/catalog\\_guidelines/catalog\\_behavioral\\_health\\_guidelines/depression/](https://www.icsi.org/guidelines_more/catalog_guidelines_and_more/catalog_guidelines/catalog_behavioral_health_guidelines/depression/)

In screening for and monitoring depression, ICSI recommends using a standardized instrument to document symptoms and baseline severity to assist in monitoring response and remission rates. Screening should be completed if depression is suspected based on certain risk factors including substance use disorder, diabetes, cardiovascular disease, and chronic pain. The cultural background of the patients should be taken into account when assessing and treating depression. The physician or office staff must document the patient's symptoms based on DSM-5 criteria and track progress and remission throughout the course of treatment. The PCP should supplement medication with psychotherapy and work with the patient to adjust medication dosage, if necessary.

## 5. Coverage and Reimbursement Policies

---

While most efforts to integrate behavioral health into primary care are at the practice or health system level, two private national payers (Aetna, Anthem) offer programs in support of collaborative or integrated care. These and some other regional (Tufts Health Plan, Blue Cross Blue Shield of Massachusetts) and national payers (Humana, United Healthcare) have divisions within the overall organization that provide behavioral health services to some portion of the plan's members, so both physical health and behavioral health care are provided under the same umbrella organization, potentially reducing restrictions on data sharing and care coordination that are more common under carve-out arrangements. Nonetheless, for behavioral health providers who are paid on a FFS basis, payers have been limited in the extent to which they can provide incentives for integrated care.

Since payer policies are continually evolving and information is not always publicly available, this section is not intended to be a complete picture of private and public payer efforts related to BHI. Rather, this section includes information on publicly available billing requirements/restrictions from payers and information on their support of BHI as of the date of this report.

Medicaid programs have more payment restrictions (e.g., on the types of providers who can bill for behavioral health services in primary care, types of visits that can be billed by an FQHC on the same day, billing codes that can be used) than do private payers. Some private payers are currently or have been involved in integrated care pilot projects that involve different payment structures and incentives.

### 5.1 Public Payers

#### State Medicaid Programs

Coverage and credentialing for billable mental health services varies widely across the New England states. Of the six state Medicaid programs, Vermont, Maine, and Connecticut have activated the HBAI codes. This six code series was created to allow providers to bill for services that support assessment and intervention of the psychological and social factors that affect treatment in patients with a primary physical health diagnosis. Patients do not need to have a behavioral health diagnosis.<sup>98</sup> Codes are available for individual assessments and reassessments that can be billed in 15 minute increments to allow for brief consultations, interventions at an individual level, and group therapy sessions. Separate codes are also available for family therapy interventions either with or without the patient. Connecticut has activated all six of the codes, while Vermont and

Maine have activated five of the six codes, excluding the code that allows for family therapy in the absence of the patient.<sup>99-101</sup> The remaining New England states have not activated the codes.

The states vary in requirements for the credentials providers must have when billing for certain services (see Table 6 below). Maine allows only psychiatrists to bill for psychiatric evaluation with or without medication management, while Vermont also allows physicians, Pas, or psychiatric NPs to bill for these services. A number of providers are able to bill for therapy services in each state, including LCSWs and PhD or PsyD psychologists. In some states, a physician, PA, NP, master’s level psychologist, or other medical professional may bill for these services. In all states except Connecticut, group therapy services are not billable, and case management is not billable in any of the six states.

**Table 6. Billing for Behavioral Health Services in FQHC Settings: State Medicaid Regulations**

	Service	VT	NH	ME	MA	CT	RI
<b>HBAI Codes</b>	Assessment	MD, PA, NP, clinical psychologist	Not activated	MD, PA, APRN, Clinical Psychologist, LCSW, LCPC	Not activated	Credentialing information not available	Not activated
	Reassessment						
	Individual Treatment

	Crisis intervention						
	Case management					Not covered	

Source: [SAMHSA-HRSA CIHS State Billing and Financial Worksheets. July 2014.](#)<sup>102</sup>

Vermont, Maine, and Connecticut Medicaid programs each cover some mental health services delivered through telemedicine. Vermont allows for evaluation with or without medical services by either a psychiatrist or NP, as well as therapy services by a physician, NP, PA, nurse-midwife, clinical nurse specialist (CNS), psychologist, or LCSW and other outpatient services by a physician, NP, or PA. Maine allows psychiatrists to bill for remote psychological evaluation without medical management. Therapy services can be billed for by a licensed clinical psychologist, LCSW, a clinical professional counselor, or a CNS. Medicaid programs in New Hampshire, Massachusetts, and Rhode Island do not currently reimburse telemedicine services, though Massachusetts and Rhode Island have both previously introduced bills to require Medicaid reimbursement of telemedicine services.<sup>102</sup> Maine and Vermont have both passed telemedicine parity laws which require that billed services be reimbursed at a rate that is on par with reimbursement for in-person services.<sup>77</sup>

Coverage for same-day services varies by payer and health care setting. However, all New England state Medicaid programs allow for same-day billing for physical and behavioral health visits in FQHC settings.<sup>86</sup>

## Medicare

In general, Medicare covers more services related to behavioral health than do a majority of New England state Medicaid programs. Medicare provides coverage for the same five HBAI codes as Vermont and Maine, but services can only be billed by doctorate level psychologists. If permitted by state FQHC billing rules, a physician, NP, PA, or CNS may bill for psychiatric evaluation performed in a primary care setting. These same providers, as well as psychologists and LCSWs, may also bill for therapy, group therapy, crisis intervention, and mental health assessment services in primary care settings as permitted by state FQHC regulations. Medicare also reimburses for telemedicine services related to behavioral health. A physician, NP, PA, CNS, clinical psychologist, or LCSW may bill for psychological evaluation without medical services, while a physician, NP, PA, or CNS can provide evaluation with medical services. A psychiatrist, NP, or clinical psychologist can provide therapy via telemedicine.

Medicare FFS plans allow for same-day billing of mental health and physical health services.

- SAMHSA-HRSA CIHS same day billing analysis: <http://www.integration.samhsa.gov/financing/Same-Day-Billing-Fact-Sheet-ICN908978.pdf>

## 5.2 Private Payers

### Regional Private Payers

Although all regional private payers have made efforts to integrate behavioral health services, there is considerable variability among them with regard to how these benefits are paid for and administered. Several plans use behavioral health “carve out” organizations to manage mental health and substance abuse services for their members, while others have developed in-house initiatives based on alternative payment methodology.

Of those plans with designated carve-outs, both Neighborhood Health Plan of Rhode Island (NHPRI) and Neighborhood Health Plan (based in Massachusetts) contract with Beacon Health Options, while Connecticare and Harvard Pilgrim Health Care (HPHC) use Optum to manage their behavioral health programs. Beacon Health Options offers members behavioral health case management services in which members are assigned a case manager to assist the patient and their family in accessing behavioral health care. Beacon does not require pre-authorization for a patient’s first 12 outpatient behavioral health visits, and members may self-refer for behavioral health services.<sup>103</sup> Under Optum, patients do not need a referral for routine outpatient behavioral health services such as medication management, psychiatric consultation and evaluation, substance abuse treatment, and therapy sessions; non-routine services require prior authorization, however.

Very little information is publicly available with regard to payment models for these carve-outs, though several plans offer additional incentives directly to primary care providers for meeting quality measures associated with behavioral health integration. HPHC, for example, has allocated several Quality Grants to primary care practices (many of which are PCMHs) that add a behaviorist to an existing care team or implement screening for depression and substance abuse.<sup>104</sup> NHPRI will also reimburse some behavioral health services when they are administered through an in-network PCP<sup>103</sup> while Connecticare covers screening for depression and alcohol abuse as a preventive service when administered in a primary care setting.<sup>105</sup>

Blue Cross Blue Shield of Massachusetts (BCBS MA) and Tufts Health Plan are unique among the New England private payers in offering in-house behavioral health services. In 2009, BCBS MA implemented the Alternative Quality Contract (AQC),<sup>106</sup> which utilizes a global payment methodology designed to include inpatient, outpatient, pharmacy, behavioral health, and other costs and services associated with each of their members while hitting quality targets. These payments are supplemented with a per-patient payment through performance-based incentives that are based on a provider’s ability to meet a number of clinical performance measures related to process, outcomes, and patient experience. Similarly, Tufts Health Plan has integrated and fully managed mental health and substance abuse benefits and services, which allows members to self-refer, or contact their PCP or the Tufts Health Plan Mental Health Department for help in choosing a

network provider.<sup>107</sup> However, some pre-authorization is required for mental health services under some commercial plans depending on product, and type and location of treatment. Tufts Health Plan's Coordinated Care Model, which aligns with ACO principles, is built on a tiered approach to cost-sharing and pays providers on a value basis, rather than through FFS.<sup>108</sup>

## National Private Payers

### *Aetna*

Aetna offers PCPs a depression program that screens and triages members to appropriate levels of care. Participating physicians screen patients for depression with validated screening tools and refer those who test positive to Aetna care planning and case management staff. The plan also identifies patients for screening based on data from its in-house pharmacy benefits manager (PBM) program, as well as by a patient's comorbid conditions. Aetna staff contact patients via telephone at multiple points after treatment and re-administer a depression screening tool (the PHQ-9, a nine item questionnaire). Physicians may consult with an Aetna psychiatrist at any time and may refer their patients to behavioral health specialists with optional assistance from a care manager.<sup>109</sup>

- Aetna Depression in Primary Care Program: <http://www.aetna.com/healthcare-professionals/documents-forms/depression-program.pdf>

### *Anthem*

Anthem offers its Enhanced Personal Health Care (EPHC) program to PCPs who are encouraged to screen for depression, alcohol, and drug use, and to promote the use of self-management techniques. Anthem staff support implementation efforts by providing consultation for workflow and process improvement, data analysis, and care management and coordination skill development. All participating providers must use a suite of web-based tools that include a record of all health care services received by their Anthem patients both within and outside of the provider's organization.

Practices that participate in the EPHC program may receive care coordination payments on a PMPM basis, though Anthem notes that local regulation and existing contracts may preclude these payments. Providers who meet both cost and quality targets are eligible for shared savings. Anthem offers EPHC programs in several states including Connecticut, Maine, and New Hampshire.

- Patient-Centered Primary Care Collaborative summary of Anthem EPHC program: <https://www.pcpcc.org/initiative/anthem-enhanced-personal-health-care>
- EPHC Program Description: [http://www.anthem.com/ca/provider/f2/s2/t1/pw\\_e191769.pdf?refer=provider](http://www.anthem.com/ca/provider/f2/s2/t1/pw_e191769.pdf?refer=provider)

## *Cigna*

Cigna offers a Collaborative Care Program in several states nationally, including Connecticut, Maine, Massachusetts, New Hampshire, and Vermont, in which physician-led care teams with care coordinators employed by the provider receive support from Cigna case managers to link patients to the clinical support programs for chronic condition management or lifestyle management offered by the payer. Medical groups participate in a pay-for-value structure linked to improved outcomes and lower costs.

- Patient-Centered Primary Care Collaborative summary of Cigna's Collaborative Care Program: <https://www.pcpcc.org/initiative/cigna-collaborative-care-program>

## *Humana*

Humana manages its Integrated Medical and Behavioral Health (IMBH) program through a subsidiary, LifeSynch. The program focuses primarily on case management services provided by medical case managers from Humana and behavioral case managers from LifeSynch.<sup>109</sup>

# 7. Evidence Review (Methods & Results)

---

## 7.1 Effectiveness of Programs that Integrate Behavioral Health into Primary Care

Our review of the evidence on the effectiveness of programs that integrate behavioral health into primary care can be found in the sections that follow. Note that, because of our focus on studies of BHI in a primary care setting and the requirement that a majority of patients have a depression and/or anxiety diagnosis, the vast majority of available studies focused on *mental health* services provided to these patients—in other words, treatment for substance use disorders as well as interventions for other behavioral issues were not a focus of these studies.

### Methods

A number of systematic reviews have assessed the effectiveness of BHI in the primary care setting among patients with depression and/or anxiety disorders. Findings from these reviews indicate that integrating mental health into primary care improves mental health outcomes such as depression and anxiety, although the effects of integration are relatively modest.<sup>109-130</sup> Because of the wealth of prior systematic reviews, we elected to focus our assessment of key systematic reviews as well as an updated search of more recently-published literature (see below).

We focused on two large, higher-quality systematic reviews from AHRQ (2008)<sup>109</sup> and the Cochrane Collaboration (2006, 2012 update)<sup>110,113</sup> that matched our project scope: a) use of an intervention that matched one of the six levels of collaboration/integration in the SAMHSA-HRSA CIHS framework (see Section 1.2), b) delivery of the intervention predominantly in the primary care setting, c) ≥50% of the population diagnosed with depression and/or anxiety disorders, and d) minimum of 6 months of follow-up in available studies.

We also conducted an updated systematic literature search using the search criteria from the 2012 Cochrane review<sup>1</sup> that covered the period from December 2013 to February 2015. The search identified additional publications from studies already identified in the AHRQ and Cochrane reviews but no new randomized trials.

The quality of individual studies was assessed by considering the domains listed below, which are adapted from AHRQ's methods guide:<sup>131</sup>

- Similarity of baseline characteristics and prognostic factors between comparison groups
- Well-described methods for randomization and concealment of treatment assignment
- Use of valid, well-described primary outcomes
- Blinding of subjects, providers, and outcome assessors

- Intent-to-treat analysis (all randomized subjects included)
- Limited and non-differential loss to follow-up
- Disclosure of any conflicts of interest

There was no way to blind participants to their group assignment in studies of integrated care. This is particularly important in studies of depression and anxiety because outcome assessment is subjective and in part based on patient report of symptoms. Thus, all of the studies have some risk for bias.

We used the ICER Evidence Rating Matrix to evaluate the evidence for the impact of integrated care on depression, anxiety, quality of life and other outcomes ([ICER Evidence Rating Matrix](#)).<sup>132</sup> The evidence rating reflects a joint judgment of two critical components:

- a) The **magnitude** of the difference between a therapeutic agent and its comparator in “net health benefit” – the balance between clinical benefits and risks and/or adverse effects AND
- b) The level of **certainty** in the best point estimate of net health benefit.

The matrix is depicted in graphic form as in Figure 4 on the next page.

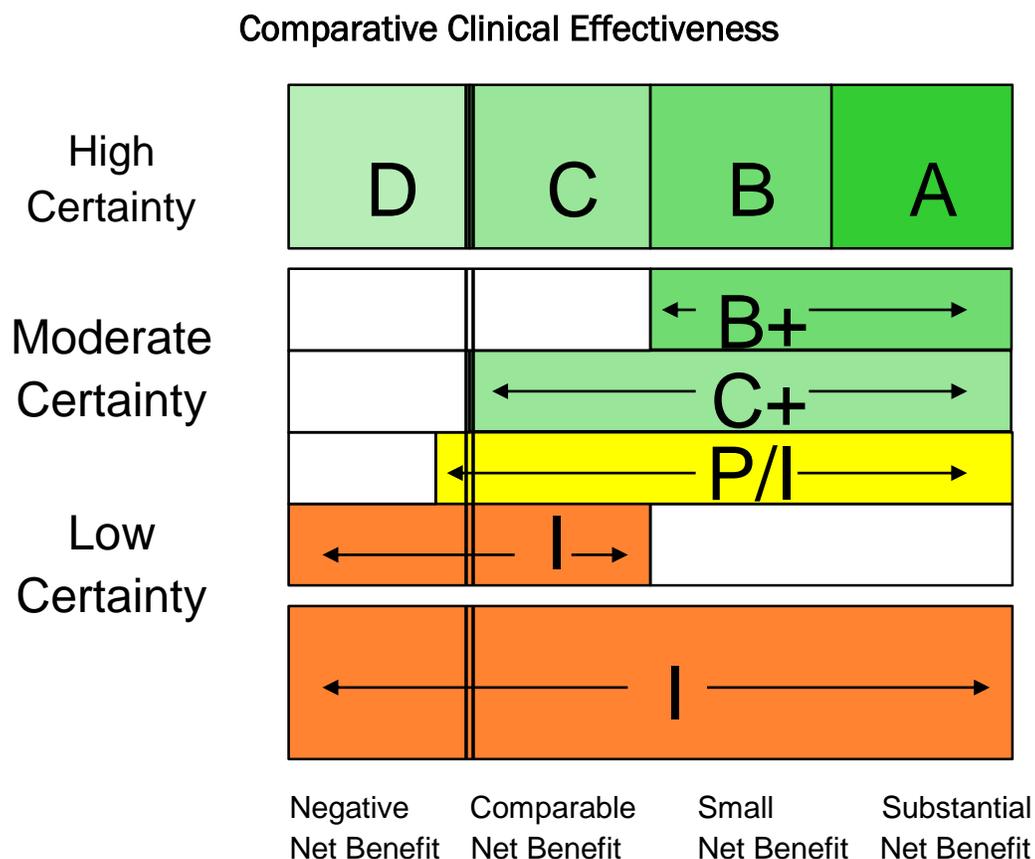

## Results

We identified 94 studies of integrated care for mental health outcomes. The large majority evaluated integrated care in primary care clinics (83%, 78/94). Five studies were initiated in the hospital and managed outside of primary care (three for cardiac disease, two for trauma focusing on PTSD prevention). Eight studies evaluated integrated care in specialty clinics (four oncology, two neurology, one HIV, and one occupational health).

Cluster randomization was used in 24% of the studies (23/94). The remainder used simple randomization at the patient level. Most of the studies were done in the US (73%), but there were 10 studies from the United Kingdom (UK), five from the Netherlands, and three from Chile.

Integrated care focused solely on medication management in 38% of the studies, psychological therapy in 12% of the studies, and both were available but not used for all patients in 50% of the studies. The case manager had professional training in psychological care in 57% of the studies. The comparison group was usual care or enhanced usual care. Usual care was almost always coordinated care with separate locations for primary care and mental health and limited communication between the two. In some studies, there was systematic screening for depression or anxiety with notification of patients and/or their PCPs about the diagnosis. This is referred to as enhanced usual care.

Figure 4: ICER Evidence-Based Medicine (EBM) Matrix

**A = "Superior"** - High certainty of a substantial (moderate-large) net health benefit

**B = "Incremental"** - High certainty of a small net health benefit

**C = "Comparable"** - High certainty of a comparable net health benefit

**D = "Negative"** - High certainty of an inferior net health benefit

**B+ = "Incremental or Better"** - Moderate certainty of a small net health benefit, with high certainty of at least incremental net health benefit

**C+ = "Comparable or Better"** - Moderate certainty of a comparable net health benefit, with high certainty of at least comparable net health benefit

**P/I = "Promising but Inconclusive"** - Moderate certainty of a small or substantial net health benefit, small (but nonzero) likelihood of a negative net health benefit

**I = "Insufficient"** - Either moderate certainty that the best point estimate of comparative net health benefit is comparable or inferior; or any situation in which the level of certainty in the evidence is low

The 2008 AHRQ review focused on randomized and high quality quasi-experimental design studies performed in the US.<sup>109</sup> For their review, AHRQ considered family physicians and general internists to be PCPs. Mental health specialists included psychiatrists, psychologists, social workers, and psychiatric nurses. AHRQ defined four levels of integrated care based on 1) the degree of shared decision-making between specialists and primary care, and 2) co-location of primary care and specialists. Their four categories, from least integrated to most, are: 1) PCP-directed care with specialist care offsite ("low" integration), 2) coordinated decision-making and off site specialty

services OR PCP-directed decision-making and on-site specialty services (“intermediate II” integration, 3) coordinated decision-making and on-site specialty services (“intermediate I” integration), and 4) consensus decision-making and on-site specialty services (“high” integration). While no formal crosswalk to the SAMHSA-HRSA CIHS framework that is used in this assessment has been published, AHRQ’s low integration roughly corresponds to SAMHSA-HRSA CIHS level 1 (minimal collaboration), intermediate II integration corresponds to SAMHSA-HRSA CIHS levels 2 and 3 (basic collaboration), intermediate I integration approximates SAMHSA-HRSA CIHS level 4 (close collaboration/co-located care), and high integration represents SAMHSA-HRSA CIHS levels 5 and 6 (integrated care).

The AHRQ review found substantial evidence that integrated care improved mental health outcomes. The bulk of the evidence was for depression, but integration also improved outcomes for patients with anxiety disorders. The studies reported that integrated care improved symptom severity, treatment response, and remission compared with usual care.

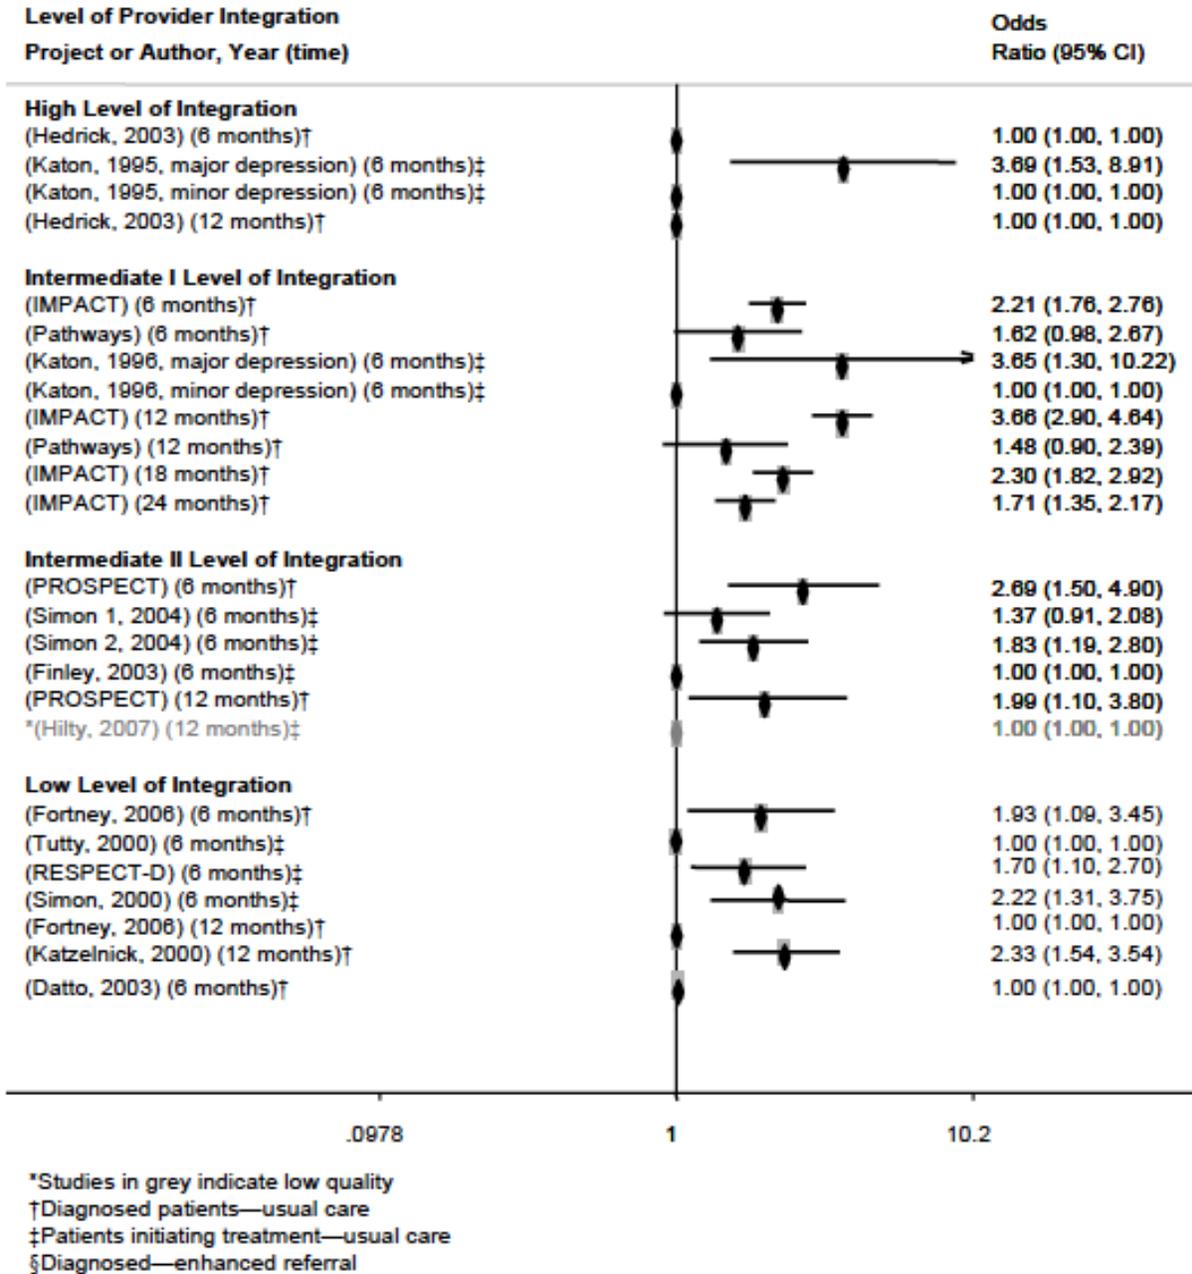

An earlier systematic review and meta-analysis of integrated care published in 2006 focused solely on depression.<sup>113</sup> The authors found strong evidence of benefit from 6 months to two years, and fewer studies, and weaker, though still significant benefit through 5 years of follow-up (see detailed findings in the sections that follow). They did not find evidence of publication bias. The Cochrane Collaboration published an updated systematic review of mental health integration into primary care in 2012.<sup>110</sup> Their search results demonstrate the depth and breadth of the literature on this topic. They identified 435 articles describing 79 randomized trials. The same group performed a more detailed meta-analysis focused on depression in order to identify factors associated with better outcomes.<sup>117</sup> The results of these new meta-analyses are described according to key outcomes of interest beginning on page 36.

### Correlation Between Levels of Integration and Outcome

The vast majority of the intervention arms for the trials included in this assessment could be classified as SAMHSA-HRSA co-located care (either basic collaboration on-site or close collaboration with some system integration), making comparisons to lower and/or higher levels of integration challenging. AHRQ’s own approach to categorization of the intensity of integration based on the decision-making process and co-location of services (described above) found no correlation between the intensity of integration and the rates of depression response or remission.<sup>109</sup> Figure 5 from the AHRQ review, replicated on the next page, demonstrates graphically the lack of correlation between level of integration and treatment response.

In addition, there are no head-to-head trials directly comparing higher levels of integration to intermediate levels of integration. Thus, there is insufficient evidence to assess whether higher levels or intensity of integration offer incremental benefit.

**Figure 5: Treatment Response by Level of Provider Integration**

## 7.2 Overall Impact of Integrated Care: Key Outcomes

### Depression

As noted above, there are a large number of randomized trials of integrated care for depression. The 2006 cumulative meta-analysis estimated that the randomized trial evidence on the mental health benefits of integrated care over usual care was statistically significant by the year 2000.<sup>118</sup> Since then, at least 56 additional randomized trials have been published, the vast majority of which demonstrated improvements in depression outcomes with integrated care compared with usual care. Three of the larger trials are described in brief below, followed by the summary statistics from the meta-analysis.

The Partners in Care (PIC) trial was a large randomized trial that influenced subsequent trials of integrated care.<sup>133</sup> Forty-six primary care clinics in six US managed care organizations were randomized to either one of two quality improvement (QI) programs or usual care. The QI programs included training local experts and nurse specialists to provide clinician and patient education, identification of a pool of potentially depressed patients, and either nurses for medication follow-up or access to trained psychotherapists. Usual care included mailing practice guidelines for depression to providers. The QI-meds intervention focused on enhancing tools for supporting medical management of depression. The QI-therapy intervention focused on enhancing tools for providing cognitive behavioral therapy (CBT) for depression. Both aimed to increase the initiation of and adherence to antidepressant medications or psychotherapy. The two interventions were combined to test their primary hypothesis: that a QI program would improve depression quality of care and patient outcomes. Patients in QI (n = 913) and control (n = 443) clinics did not differ significantly at baseline in service use, quality of life, or employment. At 6 months, 50.9% of QI patients and 39.7% of controls had counseling or used antidepressant medication at an appropriate dosage ( $P < .001$ ), with a similar pattern at 12 months (59.2% vs 50.1%;  $P = .006$ ). There were no differences in probability of having any medical visit at any point (each  $P > \text{or} = .21$ ). At 6 months, 47.5% of QI patients and 36.6% of controls had a medical visit for mental health problems ( $P = .001$ ), and QI patients were more likely to see a mental health specialist at 6 months (39.8% vs 27.2%;  $P < .001$ ) and at 12 months (29.1% vs 22.7%;  $P = .03$ ). At 6 months, 39.9% of QI patients and 49.9% of controls still met criteria for probable depressive disorder ( $P = .001$ ), with a similar pattern at 12 months (41.6% vs 51.2%;  $P = .005$ ). Initially employed QI patients were more likely to be working at 12 months relative to controls ( $P = .05$ ).

A second example is the IMPACT trial, which incorporated what was learned from the PIC trial and is the largest of the randomized trials.<sup>134</sup> It has become a resource for subsequent clinical trials and for organizations attempting to implement meaningful integrated mental health care (see website: <http://impact-uw.org/about/>). The study randomized 18 clinics and followed 1,801 depressed older adults for two years in the primary analysis. Depressed patients were identified either by their PCP

or through systematic screening using the PRIME-MD 2 question screening instrument.<sup>91</sup> The 18 participating clinics were associated with eight health care organizations in Washington, California, Texas, Indiana, and North Carolina and included health maintenance organizations (HMOs), traditional FFS clinics, an independent provider association, an inner-city public health clinic, and two VA clinics. Intervention patients had access for up to 12 months to a depression care manager who was supervised by a psychiatrist and a primary care expert. The care manager offered education, care management, and support of antidepressant management by the patient's PCP or brief psychotherapy for depression – Problem Solving Treatment in Primary Care (PST). The control group received enhanced usual care because patients were informed of their diagnosis and encouraged to seek treatment from their PCP. Depression scores using the symptom checklist 20<sup>136</sup> (SCL-20) in the intervention group declined from 1.68 at baseline to 0.99 at one year, and the score for those in the control group declined from 1.67 to 1.39 (p for between group differences < 0.001). The percentage of patients responding to treatment (at least a 50% reduction in depression score) was 45% in the intervention group and 19% in the control group (p<0.001).

Finally, the Quality Enhancement by Strategic Teaming (QuEST) trial randomized 12 clinics across the US that did not have mental health clinicians on site.<sup>137</sup> Clinics randomized to the intervention received a brief training program to two PCPs, one nurse, and one administrative staff member focused on the identification and management of major depression. Administrative staff at both the intervention and usual care sites screened patients for depression. Patients already on treatment were included in the study. In patients beginning a new treatment episode, their average depression score on the Center for Epidemiologic Studies – Depression (CES-D) scale<sup>138</sup> decreased from 55.1 to 33.4 in the intervention arm and from 52.7 to 39.2 in the usual care arm. Thus, the intervention improved depression symptoms by 8.2 points more than usual care (95% confidence interval [CI], 0.2 to 16.1; P =.04). Within this group, the intervention improved depression symptoms by 16.2 points (95% CI, 4.5 to 27.9; P =.007), physical role functioning by 14.1 points (95% CI, 1.1 to 29.2; P =.07), and satisfaction with care (P =.02) for patients who reported antidepressant medication was an acceptable treatment at baseline. In the QuEST study, patients already in treatment at enrollment did not benefit from the intervention.

The 79 studies identified for this assessment used many different validated tools to assess depression (e.g., HAM-D, CES-D, PHQ-9). In order to compare and combine the results across studies, the meta-analysis used an outcome called the standardized mean difference (SMD). This is a standard technique used in meta-analysis to provide a uniform statistic across all studies. The SMD is defined as the difference in the mean outcome between groups divided by the standard deviation in the outcome. In essence, it represents the number of standard deviation units that separate the means in the experimental and control groups in an individual study. The SMD in depression symptoms between integrated and usual care was 0.28 (95% CI 0.23 to 0.33) in the most recent meta-analysis.<sup>117</sup> There is no standard for interpreting the magnitude of the SMD, though some authors have proposed that an SMD of 0.2 is small, 0.5 is moderate and 0.8 is large.<sup>139</sup>

Using the ICER rating, our judgment is that there is high certainty of a small net benefit for integrated care in improving symptoms of depression compared with usual care. There is high certainty of benefit because in all of the larger, well done randomized trials, the p values for greater improvements in depression scores or depression remission are low ( $<0.001$ ) and the findings are consistent in the smaller studies. However, the degree of improvement in depression for patients in the intervention group was only modestly greater than that of the usual care group (SMD  $< 0.3$ , less than half achieved remission).

## Anxiety

Only seven studies focused on anxiety (7.4%). These included studies of single types of anxiety such as panic attacks or PTSD, as well as studies allowing all forms of anxiety disorders. The SMD for anxiety symptoms was 0.33 (95% CI 0.19-0.47). The confidence interval is relatively wide reflecting the lower number of studies and fewer patients with anxiety symptoms randomized in these trials.

An example of integrated care for anxiety is from the Coordinated Anxiety Learning and Management (CALM) study.<sup>140</sup> This study randomized 17 primary care clinics in four US cities to integrated care or usual care. The study followed 1,004 patients with anxiety disorders (with or without major depression) for 3 to 18 months. PCPs identified and referred patients to the study with the assistance of an optional 5-question screening tool for anxiety.<sup>141</sup> The CALM intervention, which was modeled on the IMPACT intervention, allowed patients the choice of CBT, medication, or both by non-expert care managers who also assisted primary care clinicians in promoting adherence and optimizing medications. By six months, a larger proportion of patients in the integrated care arm achieved a response (57% compared with 37%,  $p<0.001$ ) or complete remission (43% compared with 27%,  $p<0.001$ ). Both differences remained significant at 12 and 18 months ( $p<0.001$  for all comparisons).

Overall, we judge there to be moderate certainty of a small net benefit for integrated care in improving symptoms of anxiety compared with usual care. There is moderate certainty of benefit because in the large, well done randomized trial, the p values for greater improvements in anxiety scores as well as anxiety response and remission are low ( $<0.001$ ), but there are far fewer studies than for depression. The degree of improvement in anxiety for patients in the intervention group was only modestly greater than that of the usual care group, and less than half achieved remission.

## Chronic Medical Conditions

There have been a large number of studies of the impact of integration of mental health services into primary care on diabetes outcomes. Most of the studies for other medical conditions, such as cardiovascular disease, evaluated and managed patients in the hospital or specialty clinics rather than in primary care.

Diabetes is very common in primary care, and many patients with diabetes also suffer from depression. There were sufficient published trials in 2014 to perform a meta-analysis of the trials of integrated care in patients with both depression and diabetes.<sup>111</sup> All of the studies identified patients with diabetes from registries or medical records. Two of the studies then selected patients currently on anti-depressant medication or diagnosed with depression in the past year. The remaining five screened the patients with diabetes for depression. Six of the seven studies were done in the US. As an example, in a high quality trial published in the *New England Journal of Medicine* (NEJM) by Katon and colleagues, the hemoglobin A1c decreased from 8.1% to 7.3% in the integrated care group and from 8.0% to 7.8% in the usual care group ( $p < 0.001$  for between group difference).<sup>142</sup> Patients in the integrated care group also had greater decreases in depression scores ( $p < 0.001$ ), LDL-cholesterol ( $P < 0.05$ ), and there was a trend towards a greater reduction in systolic blood pressure (between group difference of -3.4 mm Hg, 95% CI -6.9 to +0.1). Our updated search did not identify additional trials to add to this meta-analysis.

In the meta-analysis of the seven randomized trials, patients in the integrated care arms had significantly lower depression scores (SMD -0.32, 95% CI -0.11 to -0.53) and lower hemoglobin A1c levels than patients in the usual care arms (-0.33%, 95% CI -0.66% to -0.0%).<sup>111</sup> However, there was significant heterogeneity across the trials for both outcomes ( $p = 0.001$ ).

We judge there to be low certainty of a small net benefit for integrated care in improving both diabetes control and depression compared with usual care in patients with both diagnoses. The level of certainty is low because of the small number of studies and the statistical heterogeneity of the results. In addition, the change in hemoglobin A1c was of borderline statistical significance. The magnitude of the benefit (change in hemoglobin A1c) was relatively small: this is less than half that expected with the addition of a single oral agent for type 2 diabetes. These differences may translate into improvements in the microvascular and macrovascular complications that decrease the quantity and quality of life for patients with diabetes, but there have been no studies of sufficient size or length to address those questions.

### Quality of life

Many of the randomized trials of depression reported measures of quality of life. The most commonly used generic instrument was the Short Form 36 (SF36), which measures several domains including mental health and physical health.<sup>143</sup> Integrated care improved mental health quality of life more than usual care in the first 6 months, and those gains were preserved through 24 months (SMD 0.20-0.26).<sup>110</sup> The trend still favored integrated care beyond 24 months (SMD 0.10), but it was no longer statistically significant. There were no early improvements in physical health quality of life, but the differences became significant between 13 and 24 months (SMD 0.10, 95% CI 0.02 to 0.17).

We judge there to be high certainty of a small to moderate net benefit for integrated care in improving quality of life in the mental health domain compared with usual care. There is low certainty of a small net benefit for integrated care in improving quality of life in the physical health domain compared with usual care.

### Patient satisfaction

Patients in the randomized trials included in the systematic review were generally more satisfied with integrated care.<sup>110</sup> In the 34 studies that assessed patient satisfaction, 22 reported statistically significant differences in favor of integrated care, 8 reported non-significant trends toward greater satisfaction, and 4 reported non-significant trends towards decreased satisfaction. Patients were typically asked about their satisfaction using a single question (24 studies). The remaining 10 studies used validated questionnaires on patient satisfaction, such as the Client Satisfaction Questionnaire or the Patient Evaluation of General Practice Care instrument. The size of the benefit was modest but highly statistically significant (SMD 0.31, 95% CI 0.13 to 0.49). One example from a large, well done trial is patient satisfaction with depression care as described for the IMPACT trial above in the section on depression outcomes.<sup>134</sup> Patients in the intervention arm of the IMPACT trial had greater overall satisfaction (76% reporting care as very good or excellent) compared with the control group (47%,  $p < 0.001$ ).

We judge there to be high certainty of a small to moderate net benefit for integrated care in improving patient satisfaction compared with usual care. The majority of studies reported significantly greater satisfaction with care (22/34, 65%), and the summary estimate from the meta-analysis was highly significant ( $p < 0.001$ ). However the differences between the integrated care groups and the usual care groups were not large (SMD 0.31).

## **Summary**

There is a very large body of randomized trials evaluating the integration of mental health into primary care. Some models train existing staff to systematically screen for behavioral health issues, and others rely on PCPs to identify the patients. Most include some form of a care manager to ensure regular monitoring of patients for side effects and treatment response, but the level of training of the care managers varied across studies. Some interventions focused solely on anti-depressant medications, some on psychological interventions, and some used both forms of therapy. The studies generally compared interventions meeting the SAMHSA-HRSA CIHS definition of co-located care with SAMHSA-HRSA CIHS coordinated care. No studies compared SAMHSA-HRSA CIHS integrated care with co-located care. These studies of different models of integration across widely varying delivery systems demonstrate with great consistency that integrated care improves depression and anxiety outcomes, although the absolute benefits are only small to modest. Furthermore, integrated care improves patient quality of life and satisfaction with care. There is

inadequate evidence to assess whether greater integration would lead to larger improvements in outcomes.

### **7.3 Components of BHI Associated with Treatment Success**

#### Methods

Research on the impact of individual components of BHI on depression-related or other health outcomes is extremely limited. Moreover, efforts to quantitatively measure the relative contribution of each program component may be confounded by lack of detail or poor reporting (e.g., missing baseline clinical characteristics, lack of data on contact or session frequency), as well as overarching concerns of publication bias—the tendency to publish only studies with positive findings. Nevertheless, Coventry and colleagues conducted a recent meta-regression of factors of collaborative care associated with improvement in depressive symptoms and use of anti-depression medication in 74 randomized controlled trials (RCTs).<sup>117</sup> In univariable analyses, factors statistically-significantly ( $p < 0.05$ ) associated with improvement in depressive symptoms included recruitment method (systematic screening vs. clinician referral), presence of a chronic physical condition, inclusion of a structured psychological intervention alone or in combination with medication management (e.g., behavioral activation, problem solving), and scheduled (vs. ad-hoc) supervision of care coordination. However, only the presence of a structured psychological component (which occurred over 2-21 scheduled sessions, depending on the study and module used) remained significant in a multivariable model ( $p = .03$ ).

To complement Coventry et al.'s approach, we conducted an analysis of the factors of integrated care most frequently reported in studies with successful outcomes. We began our search with the 33 randomized clinical trials evaluated in the 2008 AHRQ review.<sup>109</sup> In their review, the authors distilled the various characteristics of integration programs into summary tables. Trials that incorporated more than one intervention arm were analyzed separately according to each arm's model of integrated care. From the original 33 trials, we eliminated studies that had less than six months of follow-up, included a majority of patients with mental health disorders other than anxiety or depression, included adolescent study populations, or did not show a statistically-significant impact of integration on health outcomes relative to limited interventions or usual care. Treatment success was primarily related to improvements in mental functioning scores according to validated instruments (e.g., World Health Organization Disability Scale, Hamilton Depression Rating Scale), and/or improved medication adherence. After application of all entry criteria, a total of 29 studies remained from the original AHRQ sample, encompassing 31 models of integrated care (two of which had two intervention arms with different program components).

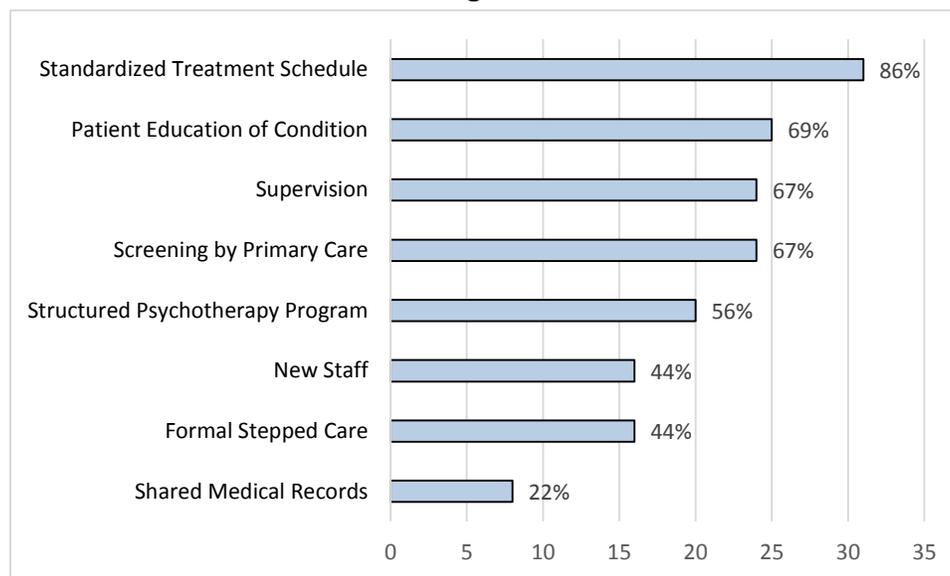

We reviewed these studies, as well as studies recommended in a list of relevant literature in a 2010 AHRQ paper discussing additional research needs on this topic.<sup>115</sup> Finally, a manual search of recent papers co-authored by the primary investigators of the original studies examined in the 2008 AHRQ review was also performed. We identified an additional five studies meeting all entry criteria and with positive findings from these channels, for an overall total of 34 studies of 36 models of integrated care.

## Study Findings

*We identified 36 models of integrated care that reported statistically-significant improvements in one or more primary outcomes of interest, such as sustained improvement in depression or anxiety symptoms, likelihood of receipt of antidepressant therapy, and medication adherence. The most common program component across successful models was inclusion of a standardized care coordination plan that involved regular interaction with both patient and physician (86%), followed by formal patient education at 69%. Both supervision of care coordinators and systematic screening in primary care were included in two-thirds of successful models, while inclusion of a standardized schedule of psychotherapy appeared in approximately half. The addition of new dedicated staff, presence of formalized stepped care plans, and use of shared medical records were the least common program components. Only two models<sup>144,145</sup> included all eight components.*

We identified 36 models of integrated care that reported statistically-significant improvements in one or more primary outcomes of interest, such as sustained improvement in depression or anxiety symptoms, likelihood of receipt of antidepressant therapy, and medication adherence. Figure 6 on the next page presents the discrete program components that we identified in available studies and the frequency with which they were reported in studies with successful outcomes. In descending order of frequency, these components included a standardized care coordination plan (i.e., scheduled interaction between a care coordinator and the patient, scheduled feedback to the clinical care team), provision of patient education of a diagnosed behavioral health condition, supervision of care coordinators, systematic screening to identify patients with behavioral health conditions in the primary care setting, availability of a structured psychotherapy program featuring a standardized schedule within the primary care setting, hiring new staff dedicated to the integration effort, formal stepped care (i.e., a protocol for care in which treatment is adjusted according to a patient's response), and shared medical records (i.e., a common information system for participating providers to track a patient's progress). A detailed examination of each of these eight components can be found in the sections that follow.

**Figure 6. Number and Frequency of Studies Identifying Selected Key Components of Integration**

### Standardized Care Coordination Plan

The most common program component found in 31 (86%) models of integrated care was a standardized protocol for interacting with patients following their initial visit. These 31 models reported having a treatment schedule in which care managers or other health care professionals, including pharmacists, nurses, or licensed therapists, had regular contact with patients about their progress. These encounters were frequently conducted via telephone, though in-person appointments were also provided depending on the patient's response to treatment.<sup>146</sup> In addition to reassessing a patient's condition, patients were sometimes given homework assignments to encourage them to remain active in their treatment.<sup>137</sup> Other programs advocated self-monitoring and allowed patients to determine their level of interaction and duration of participation according to their individualized need.<sup>147,148</sup> The details of these meetings were shared either formally or informally with other members of the patient's care team and often were entered into EHR databases. Direct contact with the PCP was somewhat less common, with the exception of situations where patients were not responding to therapy.<sup>149,150</sup> Across all models, the duration of these scheduled sessions ranged from eight weeks to one year and varied in contact frequency, though the rate of encounters generally decreased over time as the patient's condition improved and they entered a maintenance phase of care.<sup>151,152</sup>

### Patient Education of Condition

Twenty-five (69%) of the 36 models of integrated care we reviewed included a patient education component. While detailed descriptions of the particular elements of each patient education

program were limited, the timing, delivery, and content of such programs have some commonalities. Education was most often delivered through educational materials distributed to patients or through interaction with a care manager or therapist. Educational materials consisted of pamphlets, videotapes, and workbooks. These materials described the biology of a particular behavioral health condition, physical and emotional symptoms of the condition, time course and effectiveness of medication, the potential adverse effects of medication, and how both psychotherapy and medication could improve health outcomes. Education typically occurred before or during the initial phases of care, although one study specified that education was emphasized during each contact point with a patient.<sup>153</sup>

### Supervision

The reporting of supervision of staff assigned to coordinate the physical and mental health needs of patients, which was most often a care manager, was included in 24 (67%) models. In almost all models, this role was filled by a psychiatrist, even when the individual was not onsite. One program<sup>148</sup> had an offsite clinical psychologist acting as a supervisor to nurses, with weekly check-ins by telephone and one onsite visit per month. In the QuEST intervention, which sought to make only minor changes in primary care clinics to improve care for patients with major depression, the PCP supervised the clinic nurses.<sup>137</sup> Neither of these programs employed a care manager or mental health professional on site. Another program,<sup>171</sup> which was based on the Wagner chronic care model,<sup>154</sup> utilized a team of medical professionals that included a psychiatrist, psychologist, internist, and family practitioner all acting in a supervisory capacity to the care manager.

### Screening by Primary Care

Despite an emphasis on systematic screening for depression in primary care as a central component of integration, such screening was only performed in 24 (67%) of 36 successful integrated models. Other methods of identification included searches of medical databases, pharmacy records, or patient registries.<sup>155</sup> Interventions that did perform systematic screening typically cited a validated screening tool (e.g., PRIME-MD) as the method of case identification. Those conducted at VA sites had an initial assessment by a PCP,<sup>145,156,157</sup> likely due to both the influence of the IMPACT intervention,<sup>134,145</sup> in which PCPs screened participants for core depression symptoms in a baseline interview prior to providing treatment, and a high prevalence of mental health issues in VA patients. Screening appears to have been put in place in these programs primarily to identify patients with mental health conditions who are also high utilizers of health care generally.<sup>158,159</sup> However, as noted in the AHRQ review, systematic screening is only one of many elements to improve patient care, and screening alone has been shown to be ineffective in improving outcomes.<sup>109</sup>

## Structured Psychotherapy Program

There were 20 (56%) models of BHI that incorporated some form of standardized and scheduled psychotherapy into care delivery for all identified patients. These programs varied in methodology and number of sessions. Organizations that implemented variations of the IMPACT model, for example, followed a six-to-eight session model of psychotherapy developed in the United Kingdom, known as Problem Solving Therapy for Primary Care (PST-PC).<sup>147,160-162</sup> Other interventions used structured CBT,<sup>155,163-168</sup> or cognitive processing therapy.<sup>169</sup> In the TEAMcare model, patients received a less formal method of psychotherapy through “motivational and encouraging coaching” in which nurses helped patients solve problems and improve both medication adherence and self-care.<sup>142</sup> Two models of integration that were reviewed did not directly offer psychotherapy as an integral part of primary care but instead provided a “warm hand-off”<sup>170</sup> or “assisted referral”<sup>171</sup> for identified patients.

In some models where structured psychotherapy was made available, patients could decide whether or not to receive the therapy after consulting with the care team. For example, in the Prevention of Suicide in Primary Care Elderly: Collaborative Trial (PROSPECT) model, Partners in Care (PIC) model (medication arm), and the model implemented by Price and colleagues, treatment options were discussed and decided upon in collaboration with patients.<sup>164,166,172</sup> Likewise, the IMPACT model recommended psychotherapy to patients according to their preferences and response to antidepressant medications.<sup>160</sup>

Therapy was completely or partially administered by telephone<sup>162,148,173,167,155,163</sup> or interactive video conference<sup>169</sup> in several of the integrated models reviewed. One of these programs<sup>167</sup> provided six half-hour cognitive-behavioral sessions delivered over the telephone by a master’s-level therapist trained in counseling psychology. Another model, from the Collaborative Care for Anxiety and Panic (CCAP) study, allowed patients who completed at least three CBT sessions in person to receive subsequent sessions over the telephone. In addition, patients received “booster sessions” over the telephone “to monitor clinical status, reinforce proper medication use and cognitive-behavioral skills, and make further medication recommendations if necessary.”<sup>163</sup>

Psychotherapy sessions were delivered by a range of mental health professionals with various levels of experience and education. These were most often administered by individuals acting as care managers or behavioral health specialists, including psychologists, social workers, and nurses who had a master’s- or doctoral-level academic degree.<sup>121,147,155,173-175</sup>

## New Staff

We identified 16 (44%) programs in which new personnel were incorporated into and dedicated to the integrated care model<sup>109</sup>; the remainder focused on retraining existing staff or did not provide

detail on this component. The interventions that reported hiring new staff often did not specify the number or type of new staff members that were recruited, but many described the addition of a care manager position to the program. Care managers' roles included helping PCPs recognize behavioral health conditions, offering recommendations for treatment, monitoring symptoms and medication side effects, delivering psychotherapy, and following up with patients.<sup>174</sup> As noted by Butler et al., prior experience, education level, and training requirements of care managers varied extensively across care models, with some programs employing nurses or other medical professionals with limited mental health experience, and others appointing care managers with master's- or doctoral-level degrees in a mental health field.<sup>109</sup>

### Formal Stepped Care

The concept of formal stepped care introduces evidence-based protocols for treating patients that come from a variety of different clinical backgrounds. These formalized practices were identified in less than half (44%) of the integrated models. Programs based on the chronic care model were more likely to incorporate a stepped-care treatment algorithm based on treatment guidelines for depression in primary care settings; these were used to allow physicians and mental health providers to establish a treatment plan based on individualized patient needs.<sup>160</sup> Stepped care approaches were included in several models, including IMPACT, PROSPECT, Pathways, and QuEST, and were primarily concerned with treating critical patient subpopulations with co-occurring depression, such as the elderly<sup>145,172</sup> and those with diabetes.<sup>159</sup> The use of evidence-based stepped care approaches was also employed to measure patients' response to treatment in settings where there was no mental health provider on the integrated care team.<sup>137</sup>

### Shared Medical Records

We found only eight (22%) models of successful integrated care that reported using shared medical records. Programs that did share medical records primarily reported using EHRs to facilitate collaboration between members of the care team. For example, an offsite care team supported PTSD treatment delivered by community-based outpatient clinics (CBOCs) using EHRs in the Telemedicine Outreach for PTSD (TOP) model.<sup>169</sup> In this model, EHRs were used to recruit PTSD patients, provide feedback and treatment recommendations to CBOC providers, assess adherence to the medication regimen, determine receipt of cognitive processing therapy and psychiatric care, and evaluate therapist fidelity to the cognitive processing therapy protocol.

Shared medical records were also used to foster communication between providers. For example, the Internet-based system used in the IMPACT model reminded depression clinical specialists if enrolled patients had not yet received an initial assessment, if more than three weeks passed without a recorded contact with a patient, and if a patient had spent more than 12 weeks on "apparently ineffective treatment."<sup>158</sup> The Internet-based system also ensured that intervention

records were available to clinicians and study investigators in “real time.”<sup>160</sup> Another program used computerized charts to inform the PCP of medication changes by the pharmacist and record PCP interventions.<sup>150</sup> PCPs who participated in the Primary Care Research in Substance Abuse and Mental Health for the Elderly (PRISM-E) study documented their role in each patient’s care in the medical record and used this medium to communicate with mental health and substance use staff.<sup>176</sup>

Integrated clinics administered by the VA have also reported EHRs to be important mechanisms for improving communication between team members. For example, in a study by Hedrick and colleagues<sup>144</sup>, providers were notified of patient diagnoses and progress via their electronic records. Similarly, in the Telemedicine-Enhanced Antidepressant Management (TEAM) program, small rural primary care practices used telemedicine technologies (e.g., telephone, interactive video, the VA’s Computerized Patient Record System, and the Internet) to facilitate communication between a centrally located depression care team and primary care providers.<sup>156</sup>

## 8. Comparative Value of BHI

---

*Nearly all RCT-based economic evaluations published in the last 15 years have shown BHI to be more effective than usual care, but also more costly over 6 months – 2 years. Offsetting reductions in health care costs, when shown, have primarily occurred with specialty mental health services and in inpatient/emergency department care for specific subpopulations (e.g., patients with diabetes). Longer-term studies have demonstrated the potential for cost-neutrality or even overall cost savings, but these are relatively few in number and subject to quality concerns in some instances.*

*Nevertheless, evaluations of the cost-effectiveness of BHI have uniformly produced estimates that meet generally-accepted thresholds for cost-effective interventions in the US (\$15,000 - \$80,000 per quality-adjusted life year gained vs. usual care). In addition, while there may be substantial incremental start-up and ongoing costs for BHI in any given setting, many would argue that the increased reimbursement to cover the implementation of BHI represents an investment in primary care that is necessary and long overdue.*

As noted in this review, the integration of behavioral health into primary care practice can take many forms, which differ according to the level or type of integration, the types of staff involved, introduction of new infrastructure and services vs. extension of existing resources, and many other components. Because of this variability, we felt that development of a detailed economic model exploring the budgetary impact and/or cost-effectiveness of any one approach would have little validity for providers and policymakers who are interested in integration but not yet certain of the best approach for their organization. We did, however, estimate the PMPM budgetary impact of implementing BHI in an individual ACO based on assumed levels of implementation costs and ongoing “steady-state” costs over one year.

Instead, we focused our assessment of the comparative value of BHI primarily through a detailed analysis of the available literature on the economic impact of BHI in primary care for the treatment of depression and/or anxiety in Section 8.1; we focus attention not only on the primary findings of these studies but also on the differential impact of BHI in certain subgroups of patients, key drivers of economic impact, and any trends in comparative value over time. We also call attention to major design considerations and/or quality issues in these economic evaluations.

We also recognize, however, that organizations considering integrating behavioral health into primary care require comprehensive guidance on staffing levels, planning and other start-up costs, and ongoing costs to manage an integrated approach. While this type of detailed information is notably absent from the current published literature, there are publicly-available resources that do provide such guidance, and these resources are summarized in Section 8.2.

Finally, while the formula for estimating start-up and ongoing practice costs is highly individual to each organization, we nevertheless conducted a budgetary impact analysis from the perspective of a large Massachusetts ACO to illustrate the potential expenditures involved over a one-year start-up and roll-out period. The results of these analyses are in Section 8.3.

## 8.1 Prior Published Evidence on Comparative Value

Our literature search identified four higher-quality systematic reviews that focused specifically on the costs, budgetary impact, and/or cost-effectiveness of various approaches to integrating behavioral health into primary care specifically for patients with depressive and/or anxiety disorders.<sup>157,118,125,128</sup> While there is overlap between these reviews in the studies included, each review takes a somewhat unique approach to evaluating the evidence, so we have summarized each review and noted the distinctions between them in the sections that follow. In addition, findings from individual studies both within and outside the scope of these reviews are also summarized for their notable distinctive features (e.g., long-term follow-up, data on specific subgroups).

### Neumeyer-Gromen et al., 2004

This review involved an assessment of 10 RCTs published between 1995 and 2002 that compared broadly-defined collaborative care and disease management programs for depression to usual care, eight of which were conducted at managed care organizations in the US.<sup>125</sup> Interventions were required to a) use evidence-based treatment guidelines, b) have both provider and patient educational components, c) use population-based screening for case identification, and d) include routine reporting and feedback loops for members of the care team. Usual care involved clinical identification of cases and traditional referral to specialty mental health; provider education and treatment guidelines were included in the usual-care condition in some studies. A meta-analysis of clinical data from these studies indicated statistically-significant reductions in the likelihood of treatment failure (i.e., failure to achieve  $\geq 50\%$  improvement in depressive symptoms; rate ratio [RR] 0.75; 95% CI 0.70, 0.81) and in discontinuation of antidepressant therapy at 90 days (RR 0.59; 95% CI 0.46, 0.75) over periods of follow-up ranging from 5-24 months.

Six of the 10 RCTs involved an economic evaluation. All studies showed higher overall costs for integrated care vs. usual-care control. Five of the six presented results in terms of the incremental cost per quality-adjusted life year (QALY) gained; the remaining study calculated a cost per successfully treated patient ( $\geq 50\%$  improvement in depressive symptoms).<sup>178</sup> Study details and cost-effectiveness findings are presented in Table 7 on the following page; we updated costs to 2014 levels for each study using the medical care component of the US Consumer Price Index.<sup>179</sup> A range of results is presented for each study; this is because each study assessed either a range of estimates for depression's impact on health-related quality-of-life, different variants of the

intervention (e.g., integrated care + medication vs. integrated care + psychotherapy), different subgroups of patients (major vs. minor depression), or all three. Incremental costs varied from \$20 - \$3,900 per patient; this wide range can be explained in part by differences in the types of cost included in each evaluation. For example, four of six studies did not include inpatient costs in their estimates of the total costs of care, and despite the measurement of lost work time due to depression in most studies, only three of the six included any measurement of indirect costs in their calculations.

Estimates of cost-effectiveness also ranged widely (between \$15,000 and \$80,000 per QALY gained in 2014 dollars) but were nevertheless within widely-published thresholds for cost-effectiveness in US settings (\$50,000-\$100,000 per QALY gained). In addition to differences in cost calculations as described above, cost-effectiveness estimates were influenced by variability in intervention effect across studies as well as a broad range of assumed reductions in quality of life for a year with depression (between 0.2 and 0.4, or losses of 73 to 146 days due to depression).

**Table 7. Studies Reporting Cost-effectiveness of Integrated vs. Usual Care for Depression in Neumeyer-Gromen, 2004**

Author, Year	Sample Size	Incremental Costs of Integrated Care (2014 \$/Patient)	Cost per QALY Gained (2014 \$)
<b>Lave, 1998<sup>180</sup></b>	276		
<b>+Medication</b>		\$1,328 – \$1,494	\$16,292 - \$30,802
<b>+Psychotherapy</b>		\$1,521 - \$1,960	\$27,644 - \$61,144
<b>Simon, 2001 (a)<sup>181</sup></b>	407	\$1,603 - \$3,935	\$35,200 - \$79,200
<b>Simon, 2001 (b)<sup>182</sup></b>	228	\$568 - \$929	\$31,302 - \$62,605
<b>Schoenbaum, 2001<sup>183</sup></b>	1,356		
<b>+Medication</b>		\$666	\$24,530 - \$58,347
<b>+Psychotherapy</b>		\$771	\$15,165 - \$34,365
<b>Simon, 2002<sup>184</sup></b>	386	\$20 - \$412	\$32,475 - \$65,700

Source: Neumeyer-Gromen A, et al. Disease management programs for depression: a systematic review and meta-analysis of randomized controlled trials. *Medical Care*, 2004;42(12)1211-1221.<sup>125</sup>

In the study by Von Korff (1998), estimates of the incremental cost of BHI per successfully treated patient with major depression ranged from \$1,688 - \$2,850 in 2014 dollars (BHI appeared to be clinically inferior in patients with minor or “subthreshold” depression). This study also showed a small (~\$160) average reduction in the costs of specialty mental health visits for integrated vs. usual care, but this was outweighed by increases in the costs of medications and behavioral interventions in primary care. In fact, of the five additional studies in the table, only two showed offsets in any other category of cost. In an evaluation of 228 patients with persistent depressive symptoms,<sup>182</sup> an approximate \$100 reduction in the costs of non-mental health services was observed with integrated care; however, total outpatient costs were increased by ~\$250 due to higher mental

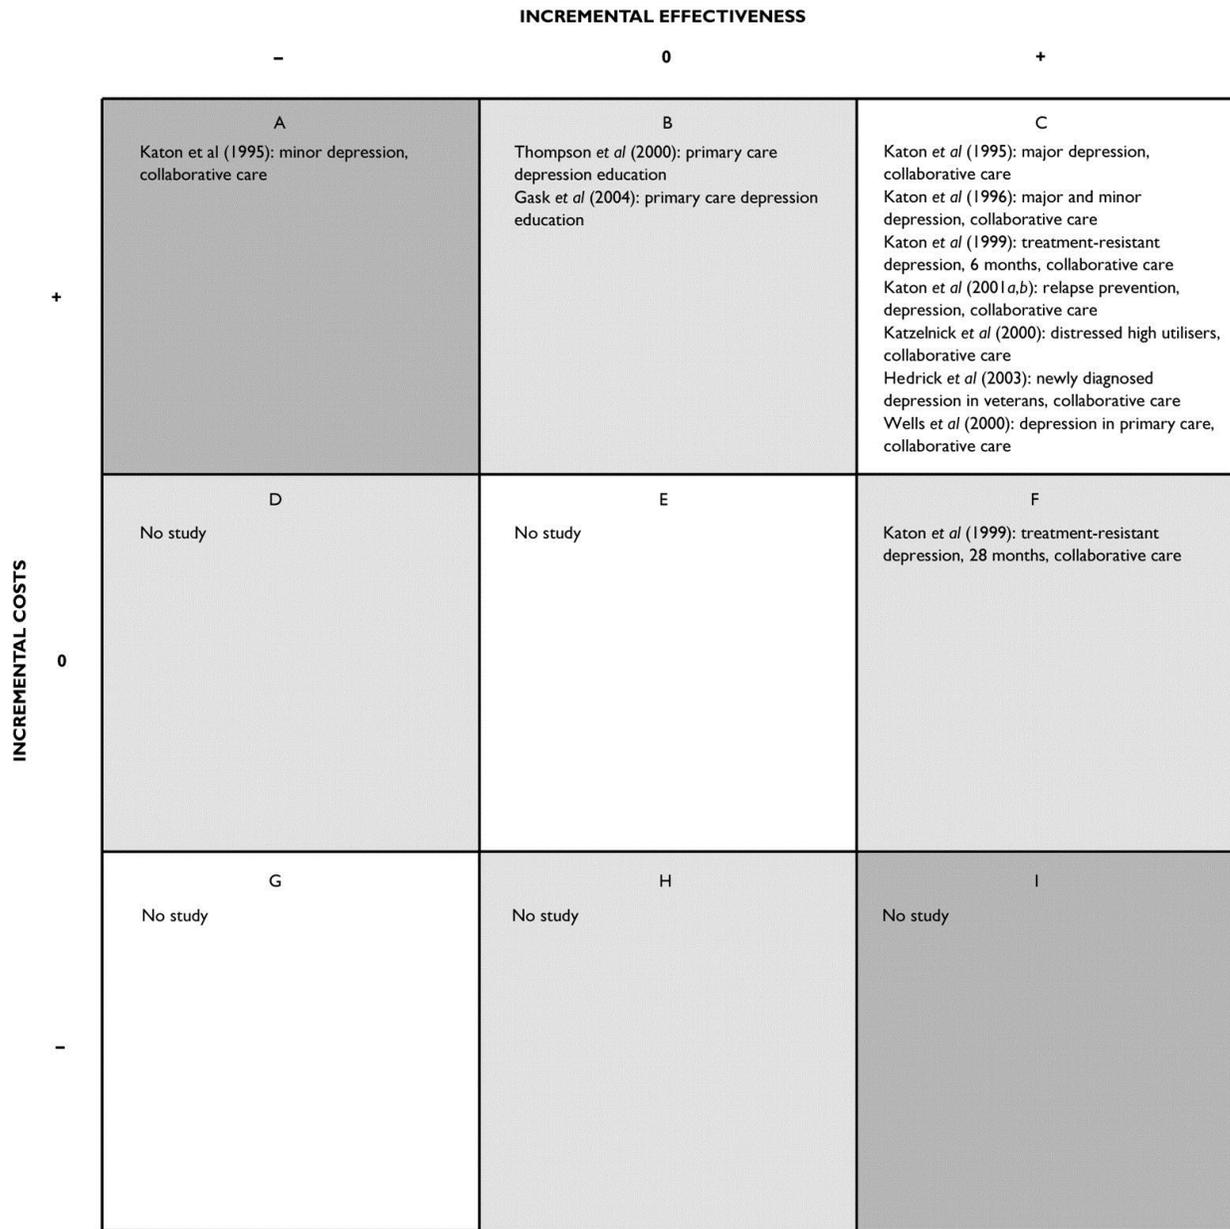

health costs. A study of BHI for relapse prevention in 386 previously-treated patients showed reductions in the cost of non-mental health services (~\$60 on average) and all inpatient care (~\$150), but these were subject to wide confidence intervals and the authors focused primarily on the increased costs of depression-related treatment in the intervention group.<sup>184</sup>

Finally, of note in these studies (and among most of the studies summarized in this section), it is likely that estimates of incremental costs are conservative because the full costs of implementing the intervention are not accounted for or not reported in sufficient detail. For example, while most of the studies presented the costs of delivering integrated care in sufficient detail, inclusion of the costs of practice-wide screening are mentioned in only two of the six studies in this review. In addition, despite the fact that these RCTs were tests of novel interventions for integrated care, the costs of planning, infrastructure changes, and implementation were not mentioned in any study.

#### Gilbody et al., 2006

This evaluation involved an assessment of a broad array of economic evaluations (including cost-benefit, cost-effectiveness, and cost-minimization analyses) of collaborative care or care management models.<sup>118</sup> Studies had to include a discrete educational intervention, a structural change or reconfiguration of roles with primary care, or a case management/active follow-up component, and be based on data obtained from a randomized study. Quality criteria specific to economic evaluations were also applied. For example, studies that did not use a well-accepted method for generating confidence intervals around estimates of economic impact (e.g., bootstrapping) were excluded. A total of 11 reports of economic evaluations were identified, including five of the six studies included in the Neumeyer-Gromen review (the Lave 1998 study was excluded for multiple reasons, including quality concerns and lack of active case management). As with the Neumeyer-Gromen review, no study produced cost estimates indicating that BHI was both more effective and less costly than usual care. Figure 7 on the next page presents a “permutation matrix” illustrating this finding. Two studies of an intervention that consisted of clinician education efforts alone showed no clinical benefit and higher costs vs. usual care.<sup>185,186</sup> The previously-described Von Korff evaluation (which was based on RCT data from Katon, 1995) illustrated that BHI for minor or subthreshold depression is both more costly and less effective. Finally, a longer-term follow-up of an above-described intervention for persistent depression<sup>138</sup> showed durable clinical benefits at 28 months and cost-neutrality – no statistically-significant differences in depression-related costs, all outpatient costs, or total health care costs between the BHI intervention and usual care.<sup>146,187</sup> All remaining evaluations produced evidence of incremental benefit and increased costs for BHI vs. usual care.

Figure 7. "Permutation Matrix" of Incremental Effectiveness and Incremental Cost

- Decision strongly favoured (A, reject treatment; I, accept treatment)
- Decision less favoured (B, D, reject treatment; F, H, accept treatment)
- No obvious decision (C, is added effect worth the extra cost? G, is reduced effect acceptable at reduced cost? E, neutral cost and effect: other reasons to adopt treatment?)

Source: Gilbody S, Bower P, Whitty P. Costs and consequences of enhanced primary care for depression. *Br J Psych* 2006; 189:297-308. <sup>213</sup>

Estimates of the incremental cost per depression-free day ranged relatively narrowly from \$17 to \$32 (2014 dollars) across available studies. Beyond those summarized in the Neumeyer-Gromen review, the only additional study to estimate the incremental cost per QALY gained was an

evaluation of a nurse-delivered case management approach in 211 patients with newly-diagnosed depression.<sup>188</sup> Cost-effectiveness was estimated to be \$22,529 per QALY gained (2014 dollars); acceptability-curve analyses conducted at the time indicated a 91% probability that cost-effectiveness would be less than \$50,000 per QALY gained.

#### van Steenberg-Weijnenburg, 2010

This review focused attention on eight economic evaluations of data from RCTs of collaborative care interventions that involved systematic and planned approaches to “stepped care” for depression in primary care (i.e., increased intensity of services for patients who screen positive).<sup>128</sup> The review is also notable for its use of a detailed published checklist for the quality of economic evaluations known as the Consensus on Health Economic Criteria (CHEC) list,<sup>189</sup> which consists of 19 yes/no questions within the following domains:

- Study design (e.g., target population, time horizon, perspective adopted, treatment alternatives of interest)
- Capture and appropriate measurement of relevant costs
- Capture and appropriate valuation of health outcomes
- Analytic approach (e.g., discounting, incremental comparisons)
- Assessment of uncertainty
- Reporting issues (e.g., generalizability, conflicts of interest)

Five of the eight studies were also included in one or both of the reviews from Gilbody and Neumeyer-Gromen. The three additional studies included a 6-month assessment of group-based BHI among 240 adult women with depression in Chile,<sup>217</sup> and two evaluations of RCT data from two separate trials (N=1,801 and 329 respectively) of depressed patients with diabetes.<sup>218,219</sup> Both of the latter studies were conducted in US settings, were based on the University of Washington’s IMPACT model, and followed patients for 24 months. Findings from the Chilean evaluation are difficult to generalize because the costs of health care services are valued very differently so are not discussed further here. In the larger IMPACT evaluation focused on patients age >60, total outpatient and overall health care costs were increased by \$395 and \$926 respectively (2014 dollars) for the intervention relative to usual care; the cost per QALY gained (in 2014 dollars) ranged from \$3,376 - \$6,750 based on a range of assumed quality-of-life impacts from depression.<sup>219</sup> A time trend analysis suggested that the intervention was associated with reductions in total outpatient costs after 12 months of follow-up, but the impact on overall health care costs was not assessed.<sup>218</sup>

A more detailed assessment of this trend was included in the other IMPACT evaluation.<sup>219</sup> Total depression-related and unrelated outpatient costs were similar between the intervention and usual care in the first year (approximately \$9,200 [2014 dollars] per patient in each group) but were reduced by over \$1,700 in the intervention group in the second year; on average, 2-year costs were

reduced by approximately \$1,100 and \$370 in the intervention group before and after adjustment for baseline differences between groups. Reductions were driven primarily by lower costs for drugs other than antidepressants, specialty medical visits, and diagnostic services. However, as with the Katon evaluation, the impact on overall health care costs was not measured. Also, as with many of the other evaluations in these reviews, intervention costs were focused primarily on the costs of delivering services and did not appear to include practice-wide or other fixed costs associated with planning, implementation, or screening.

Across all studies, the quality of available economic evaluations was found to be lacking; the highest score observed on the CHEC list was 10 (out of 19 possible items). Most studies lacked any systematic approach to conducting sensitivity analyses for variables subject to high levels of uncertainty. Only four of the eight studies presented results using generally-accepted incremental methods and measures (e.g., cost per QALY). Studies were inconsistent in the perspective adopted, and while many studies measured lost productivity and time in treatment as outcomes, their associated costs were often not reported. Finally, the durability of intervention effects was largely unknown due to the within-RCT nature of these evaluations (i.e., maximum follow-up of 24 months).

#### de Bruin, 2011

This review focused on 31 studies of disease management programs for diabetes, depression, heart failure, and chronic obstructive pulmonary disease; the Wagner chronic care model was used to search for appropriate programs.<sup>177</sup> Four RCT-based economic evaluations in depression were identified; one was a subset analysis of the IMPACT trial for late-life depression at sites with 4-year trial data available.<sup>207</sup> The other three were reported only in this review and included a pharmacist-led intervention,<sup>190</sup> a telephone-based collaborative care program,<sup>191</sup> and an economic evaluation of Partners in Care (PIC), an educational and nurse-support intervention studied at six managed care organizations in the US.<sup>192</sup>

The pharmacist intervention was used in a 6-month RCT of 151 patients.<sup>190</sup> However, 6-month follow-up data were only available for 88 patients (58%); incremental costs of the intervention averaged \$604. However, the study found no statistically-significant improvements in either depression symptoms or medication adherence, so the incremental costs were deemed not worthy of investment by the authors. The PIC intervention was found to increase total health care costs by an average of \$1,122 (2014 dollars) in patients with major depressive disorder<sup>192</sup>; no detail was provided on individual cost components, however. The corresponding cost-effectiveness ratio (in 2014 dollars) was \$66,070 per QALY gained based on utility data derived from the Short Form (SF) 12 instrument. Incremental costs were much lower in patients with subthreshold depression (\$46 on average in 2014 dollars), as was the resulting cost-effectiveness ratio (\$2,494 per QALY gained). Of note, however, the study organizers covered 50% of the costs of intervention development and delivery, so estimates of incremental cost are likely understated.

The Simon study randomized 600 patients at Group Health Cooperative to usual care, telephone care management, or telephone care management plus short-course CBT over 24 months of follow-up.<sup>191</sup> Adjusted outpatient costs controlling for age, sex, and baseline costs were \$784 and \$461 higher for telephone management and telephone management plus psychotherapy respectively vs. usual care (2014 dollars). Unadjusted inpatient costs were tallied but were not included in multivariate analyses because of their substantial variability.

The final evaluation in this set was a 4-year study of the effects of the IMPACT intervention<sup>218</sup> at sites with cost data available over this timeframe.<sup>207</sup> The intervention was found to reduce total health care costs by \$4,035 (2014 dollars) on average; reductions were seen in every cost category but were driven primarily by lower inpatient costs (\$3,093). Temporal analyses also suggested that the cost savings occurred entirely in years 3 and 4 of the evaluation. However, the intervention itself was only one year in duration, and no long-term assessment of clinical outcomes was conducted; it is therefore impossible to ascribe cost differences definitively to a persistent treatment effect.

#### Other Studies

An RCT of “enhanced care management” involving care coordinators working with primary care physicians and mental health providers at different sites was not included in the above reviews for unknown reasons.<sup>193</sup> This study randomized 12 primary care practices to the intervention or usual care; 73% of the initial patient sample (n=211) was available for 24-month follow-up. Total costs (including intervention, outpatient, and patient time and transportation) were \$657 higher in the first year of the evaluation but \$27 lower in the second year (2014 dollars). Cost-effectiveness estimates ranged from \$12,853 per QALY gained when generic costs for antidepressants were assumed to \$19,170 per QALY gained when brand costs were assumed (2014 dollars). This study was also notable for its detailed accounting estimates of screening and intervention workflow, as illustrated in Table 8 on the following page. Interestingly, the screening tool is described in the study as a “2-stage instrument”, but the accounting estimates suggest that the office assistant spent no more than three minutes per screen.

Observational studies have also shown promising results, but design and analysis challenges limit their applicability. For example, a quasi-experimental comparison of 1,225 patients treated for depression at Intermountain Healthcare’s integrated and non-integrated clinics<sup>194</sup> indicated a smaller increase in costs between the 12 months before and after diagnosis for integrated care (\$812 vs. \$1,559 for usual care, 2014 dollars). However, the pre-diagnosis costs in the usual-care cohort were nearly 20% higher than those in the intervention group, a difference that was not controlled for in the analysis. In addition, the analysis was restricted to health plan payments, so there was no way to know what the incremental costs of delivering integrated care were.

**Table 8. Example of Accounting Approach to Estimating Costs of Delivering BHI**

<b>Activity</b>	<b>Time</b>	<b>Cost per Hour \$</b>	<b>Mean per Capita Cost \$</b>
Office assistant screening	.050 hr per screening test × 5,838 screening tests / 115*	13.91	35.28
Care manager preparation	.115 hr per contact × 11.8 contacts	24.40	33.11
Care manager contacts	.210 hr per contact × 11.8 contacts	24.40	60.46
Care manager record keeping	.165 hr per contact × 11.8 contacts	24.40	47.51
Physician review of care manager's records	.550 hr	85.51	47.03
Care manager communication with physician	.216 hr	24.40	5.27
Physician communication with care manager	.216 hr	85.51	18.47
Overhead	30% of above costs		74.14
2-year total costs			321.27
Annual costs			160.64

Note: Screening by office assistant, care manager, and physician cost per hour derived from Bureau of Labor Statistics estimate for median office assistant, registered nurse, and general/family practitioner earnings plus 25% fringe benefits inflated to year 2000 dollars. Office assistant, care manager, and physician time estimates derived from care management report.

\*Identifying 115 patients beginning a new treatment episode required screening 5,838 patients.

## 8.2 Resources for Estimating Start-Up Costs

As noted previously in this section, nearly all economic evaluations did not include a full valuation of implementation costs in their estimation of expenditures for BHI and were also lacking detail on practice-wide expenses involved in delivering the intervention (e.g., screening) in many instances. In addition, our budgetary impact analysis was based on a single scenario, and the realities of integration will vary widely by setting.

Nevertheless, publicly-available tools are available for organizations interested in BHI to develop estimates of staffing needs and expenditures for planning, start-up, and “steady state” once integration has been implemented. These tools are summarized on the next page and more detailed resources are available in Appendix B.

## Staffing

The AIMS Center at the University of Washington, the developers of the IMPACT integration model, have developed an online implementation guide for primary care organizations considering BHI. The full implementation guide can be found at: <http://aims.uw.edu/collaborative-care/implementation-guide>. As part of this effort, the AIMS team has developed a staffing formula for diverse primary-care settings based on the mental health needs of the populations being served (low, medium, or high). The formula is depicted in Table 9 below.

**Table 9. Collaborative Care for Depression: Staffing Ratios in Diverse Clinic Settings**

Clinic Population	Prevalence of Depression	Typical Active Caseload for 1 FTE Care Manager	Primary Care Panel Size for 1 FTE Care Manager	Typical Personnel Requirements for 1,000 Primary Care Patients (FTEs)	
				Care Manager	Psychiatric Consultant
<b>Low need (e.g., insured, employed)</b>	2%	100-125	5,000	0.2	0.05 (2 hrs/wk)
<b>Medium need (e.g., FQHC, chronic pain, substance use)</b>	5%	65-85	1,500	0.7	0.07 (3 hrs/wk)
<b>High need (e.g., homeless, addiction issues)</b>	15%	50	333	3.0	0.3 (12 hrs/wk)

FTE: Full-time equivalent; FQHC: Federally-qualified health center

©2014 University of Washington

In addition, SAMHSA-HRSA CIHS developed an implementation and financing guide specifically for FQHCs. The guide cites a general rule that behavioral health staff “should be available 2-4 hours weekly for every 1,000 primary care patients,”<sup>195</sup> although the source of this information is cited only as personal communication. The full guide can be found at:

[http://www.integration.samhsa.gov/financing/Financing\\_BH\\_Services\\_at\\_FQHCs\\_Final\\_7\\_23-12.pdf](http://www.integration.samhsa.gov/financing/Financing_BH_Services_at_FQHCs_Final_7_23-12.pdf).

## Estimating Planning, Implementation, and Steady-State Costs

Prescription for Health is a grant-making organization based at the University of Colorado-Denver that is focused on incorporating evidence-based methods to encourage patient behavior change in clinical practice (<http://www.prescriptionforhealth.org/about/index.html>). One of the results from the initial two rounds of funding was an Excel-based toolkit for organizations interested in integrating behavioral health into primary care; the resulting estimates of start-up costs have been published and are described in further detail in Section 8.3.<sup>196</sup> The toolkit consists of multiple worksheets that allow for estimation of planning, start-up, and ongoing costs of a BHI program based on the needs and infrastructure of individual organizations. The toolkit was recently modified for use with Colorado's Advancing Care Together (ACT) initiative, which involves BHI integration at 11 diverse practice sites across the state.<sup>197</sup> Examples of detailed templates can be found in Appendix B. Briefly, the templates are designed to capture the following cost elements:

### Planning Costs

- Current patient flow
- Current staff salaries, FTEs, fringe percentages, etc.
- Amount of time spent on BHI planning for each staff type
- Current direct expenditures, indirect expenses, and overhead

### Start-Up Costs

- Staff training (e.g., screening tool, program activities)
- Administration (e.g., website redesign, community outreach)
- Fixed costs (e.g., workspace, computer equipment, other capital assets)
- Overhead (e.g., rent/lease, insurance, phone and utilities)

### "Steady State" Costs

- Percent of staff time devoted to intervention and incremental costs associated with treatment
- Overhead expenses attributable to BHI
- New capital purchases and depreciation of existing assets

SAMHSA-HRSA CIHS has also developed a resource for making the business case for BHI. However, the focus of this tool is on modeling improvements in workflow and revenue through use of additional billing codes, reducing PCP time for case triaged to a behaviorist, etc. While there are entries for development, implementation, and screening costs, they lack the level of detail described above. Nevertheless, the Excel-based pro forma tool can be found in Appendix C to this report, and the full monograph on the business case can be found at:

[http://www.integration.samhsa.gov/integrated-care-models/The Business Case for Behavioral Health Care Monograph.pdf](http://www.integration.samhsa.gov/integrated-care-models/The_Business_Case_for_Behavioral_Health_Care_Monograph.pdf)).

## 8.3 Budgetary Impact Analysis

### Methods

To gain an understanding of the potential expenditures that might be involved in a new effort to integrate behavioral health into primary care practice, we conducted an exploratory analysis from the perspective of a large Massachusetts ACO (200,000 lives). Primary model inputs are presented in Table 10 on the following page. We made a number of key assumptions for this analysis, as listed below:

- ACO manages a primarily employed and privately-insured population
- Assumed start-up time of 4 months, remainder of year assumes implementation and ongoing intervention
- New hires of 40 RN care managers and 10 psychiatrist consultants required, based on recommended staffing ratios for “low need” practices from AIMS Center
- Change in job role for medical assistants to conduct depression screening; no additional hires
- Only small modifications of existing EHR system required, no other major IT expenses
- Additional capital expenditures assumed for workspace for new hires
- All patients in panel assumed to have one screening encounter during the year

Expenses were divided into those required for program implementation and start-up, and those that would be incurred after BHI is implemented (i.e., “ongoing” costs). We found a single source of published data on these costs, an analysis of the initial Prescription for Health integration of behavior-change interventions in 29 primary care practices across the US.<sup>156</sup> However, the interventions of focus in this study were limited in scope, focusing on coaching patients with regard to smoking cessation, dietary change, exercise, and alcohol use. Costs were estimated based on the experience of three of these practices (practice group 2 in the publication), which were the only ones to report capital expenditures for additional staff space.

We therefore assumed additional costs related to the integration of staff and instruments targeted at identification and treatment of depression. Requirements for new care managers and psychiatric consultants were estimated based on the staffing ratios published by the AIMS Center for “low need” organizations (see Section 8.2); we assumed that these individuals would each require four and two hours of training, respectively. As noted above, we did not assume any new hires of office/medical assistants but rather retraining of existing staff. We assumed that there would be

one assistant per 2,000 patients in the panel (100 total), and that these individuals would require 4 hours of retraining each. Training costs were calculated based on published average Massachusetts-specific wage rates for nurses, physicians, and medical assistants from the US Bureau of Labor Statistics (see Table 10 below). Care managers were assumed to be nurses as this was the most commonly reported staff type filling the role in available RCTs.

We estimated ongoing costs based on three components: screening, direct staff expenses for intervention delivery, and practice overhead. Screening costs were estimated based on the use of a validated patient instrument that required 3 minutes of office assistant and 0.5 minutes of PCP time for each screen; relevant wage rates were applied to calculate these costs. Intervention delivery costs were estimated based on a depression prevalence of 3% in this population (6,000 patients), based on data from an analysis of major depression in an employer database.<sup>198</sup> Each of the 40 care managers was therefore expected to manage an active full-time caseload of 150 patients; this caseload would also require 0.25 of a psychiatrist FTE. Overhead costs (e.g., clerical support, billing) were estimated based on the study by Dadoo and colleagues, again focusing on the experience of practice group 2.<sup>196</sup>

All costs are presented in 2014 dollars and were updated as necessary using the medical care component of the US Consumer Price Index.<sup>199</sup> Analyses were conducted using Microsoft Excel® 2013.

**Table 10. Model Inputs for Budgetary Impact Model in a 200,000-member ACO**

Parameter	Estimate	Source(s)
<b>Staffing Requirements</b>		
<b>RN Care Managers</b>	40 (0.2 per 1,000)	AIMS Center, 2014
<b>Psychiatrist Consultants</b>	10 (0.05 per 1,000)	AIMS Center, 2014
<b>Medical Assistants</b>	100 (existing)	Assumption
<b>Average Hourly Wages</b>		
<b>Medical Assistants</b>	\$18.01	US Bureau of Labor Statistics, Massachusetts, 2014
<b>RN Care Managers</b>	\$45.37	"
<b>Psychiatrists</b>	\$89.87	"
<b>Primary Care Physicians</b>	\$98.47	"
<b>General Start-Up Expenses (per month)</b>	\$5,817	Dadoo, 2008; US BLS, 2014
<b>Major Depression Prevalence</b>	3%	Ivanova, 2010
<b>General Overhead Expenses (per diagnosed and treated patient per month)</b>	\$57	Dadoo, 2008; US BLS, 2014

NOTES: Staff time for training included 4 hours for each of 40 care managers, 4 hours for each of 100 medical assistants, and 2 hours for each of 10 psychiatric consultants. Screening time included 3 minutes per test for

medical assistants and 0.5 minutes per test for primary care physicians. Active caseload of 150 patients assumed for each care manager and psychiatric consultant (1.0 and 0.25 FTE respectively).

## Results

Findings from our budgetary impact analysis are presented in Table 11 below on a total and PMPM basis. As illustrated in the table, costs during the 4-month start-up period are relatively modest (approximately \$40,000 in total, or \$0.02 PMPM), even with an assumed training of 50 new staff and retraining of 100 others. Similarly, screening costs are not a significant contributor (approximately \$340,000, \$0.14 PMPM) given the relatively small amount of assistant and PCP time that each screen takes. By contrast, direct staff and overhead costs would be expected to generate nearly \$800,000 in monthly expenditures for this ACO, or over approximately \$6.5 million during the remaining 8 months of the year (\$2.73 PMPM).

**Table 11. Start-up and Ongoing Expenses of BHI in a 200,000-member ACO**

Type of Expense	Total Cost (\$)	Total Cost (\$PMPM)
<b>Start-Up Expenses (4 months)</b>		
General startup	\$23,268	\$0.01
Additional training	\$16,261	\$0.01
<b>Total Start-Up Expenses</b>	<b>\$39,529</b>	<b>\$0.02</b>
<b>Ongoing Expenses (8 months)</b>		
Screening	\$337,652	\$0.14
Direct Staff	\$3,473,280	\$1.45
Overhead	\$2,736,000	\$1.14
<b>Total Ongoing Expenses</b>	<b>\$6,546,932</b>	<b>\$2.73</b>
<b>TOTAL FIRST-YEAR EXPENSES</b>	<b>\$6,586,461</b>	<b>\$2.74</b>

NOTE: Subtotals and grand total may not precisely sum due to rounding.

Our findings suggest that first-year expenses for a 200,000 member ACO are sizeable, even in a relatively low-risk population. The incremental PMPM expense of BHI (\$2.74) generated in this analysis represents an 11% increase over a cited primary care benchmark PMPM of \$26, which was derived based on revenue estimates from the primary care practices participating in the CMS Comprehensive Primary Care Initiative.<sup>200</sup>

As mentioned previously, the budgetary impact displayed in this analysis is illustrative for the assumed scenario only. For example, another large ACO might already have sufficient physical space and co-located behavioral health personnel, so a greater focus would be placed on reconfiguring workflow and less emphasis on new hires and changes to the physical plant. By contrast, a small ACO might need greater information technology investment as well as additional hiring and physical space modifications. In addition, our analysis assumed that all 6,000 patients

who screen positive for depression would be actively managed, which may be challenging from a throughput perspective, even with optimal staffing. Still, if only 50% of screen-positive patients received the intervention over the 8-month period after implementation, the PMPM impact would still be \$1.43, or a 6% increase over a base of \$26. However, we have also assumed no cost offsets associated with the intervention. For example, if we assumed annual costs of care of \$8,000 for the 6,000 depressed patients in our sample, and further assumed that BHI would reduce overall health care costs by only 5% in these individuals, the resulting savings (\$2.4 million) would reduce the PMPM impact of BHI by \$1 (35%).

Despite these limitations, we believe that this analysis can be instructive for both organizations considering an approach to BHI as well as to payers considering appropriate reimbursement models that would allow ACOs and other provider organizations to recover the implementation costs of BHI and sustain such interventions moving forward.

## Summary

As in ICER's recent review of newer treatments for hepatitis C for CTAF,<sup>201</sup> ICER has adopted a novel framework for assessment of the comparative value of health care interventions, in which value is assessed according to two distinct constructs:

- *Care Value:*
  1. Comparative clinical effectiveness of each intervention vs. alternatives (considering both clinical benefits and harm)
  2. Any additional "non-clinical" benefits (e.g., reduced caregiver burden)
  3. Contextual considerations (no other acceptable treatment, vulnerable populations)
  4. Cost-effectiveness (incremental cost to achieve important patient outcomes vs. alternatives)
  
- *Health System Value:*
  1. Care value of the intervention of interest (as above); and
  2. Potential effects of short-term budgetary impact from the intervention on other patients in the health care system

Our consideration of care value is based on a relatively robust evidence base for both clinical effectiveness and cost-effectiveness of BHI interventions for depression and anxiety in primary care. Available studies have been relatively consistent in showing incremental clinical benefit over usual care, at least in terms of mental health outcomes. In addition, while not explicitly measured in these studies, there does not appear to be any potential harm to the patient from integration efforts. Finally, while the quality of available economic evaluations could be greatly improved, findings from

multiple evaluations across a variety of integration models and populations suggest that BHI falls within generally-acceptable thresholds for cost-effectiveness (\$15,000 - \$80,000 per QALY gained vs. usual care).

Assessment of health system value is much more complex, however, as the investment in BHI and the potential for return on investment varies greatly depending on the realities faced in any individual setting. Economic studies have shown with consistency that BHI increases organizational costs, at least in the short term. Evidence on longer-term cost savings is more limited, focused on specific subpopulations (e.g., patients also diagnosed with diabetes) in many instances, and subject to methodological concerns in others (e.g., incomplete accounting of start-up or practice-wide costs, tracking of health care costs at periods distal to the end of the intervention). However, others would argue that the increase in PMPM costs such as those depicted in our budget impact analysis are not only manageable, they are in fact *warranted* due to chronic underfunding and undervaluing of primary care.<sup>202</sup> In addition, while there are not currently consistent data with which to estimate potential cost offsets from BHI, fairly conservative estimates of reductions in health care costs could offset these initial investments considerably. Given the broader context of increased movement toward accountable care and other at-risk arrangements, BHI is one of multiple steps that is likely to be taken.

## 9. Barriers and Potential Solutions

---

ICER staff conducted semi-structured interviews with regional and national subject matter experts and reviewed the policy literature to understand real world perspectives on practice and delivery system innovations, barriers to change, and opportunities for improving how behavioral health care services are integrated into primary care. The goals of this section are to supplement the scientific literature with a discussion of: a) the practice, policy, and financial challenges to integrating behavioral health and primary care in New England; and b) the state specific options for implementation, learning from existing models both in the region and nationally.

At the public CEPAC meeting on May 1, 2015, these barriers and potential solutions will be discussed at length with the Council and a Policy Roundtable composed of subject matter experts. CEPAC will also cast votes to assess the comparative effectiveness and value of BHI (draft questions for deliberation are posted for public comment on the CEPAC [website](#)). Following the public meeting, this section will be updated to summarize the discussion of CEPAC members and Policy Roundtable participants regarding the evidence and will include a formal set of policy recommendations related to implementing BHI.

### Methodology and Limitations

To perform this assessment we performed key informant interviews with 30 national and regional subject matter experts representing the following institutions:

<b>Academic and Research</b>	Advancing Care Together, University of Colorado
	AHRQ Integration Academy
	National Institute for Mental Health
	Institute for Healthcare Improvement
	Milliman
	University of Massachusetts Medical School, Center for Integrated Primary Care
<b>Hospital/Community Health/FQHCs</b>	Cheshire Medical Center/Dartmouth-Hitchcock Keene, New Hampshire
	Fair Haven Community Health Center, Connecticut
	Goodwin Community Health Center, New Hampshire
	Memorial Hospital of Rhode Island
	Penobscot Community Health Center, Maine
	Providence Community Health Center, Rhode Island
<b>Practice networks</b>	Cherokee Health Systems
	Intermountain Healthcare
	MaineHealth
	University of Vermont Health Network

<b>Patient/Consumer Advocate</b>	Office of Healthcare Advocate, State of Connecticut
	National Alliance of Mental Illness, Maine
<b>Payers and managed care organizations</b>	Connecticut Medicaid
	Massachusetts Behavioral Health Partnership
	Rhode Island Medicaid
	Tufts Health Plan
<b>State Policymakers</b>	Care Transformation Collaborative, State of Rhode Island
	Department of Behavioral Healthcare, Developmental Disabilities, and Hospitals, State of Rhode Island
	Department of Human Services, State of Rhode Island
	Department of Mental Health, State of Massachusetts
	Department of Social Services, State of Connecticut
	Health Policy Commission, State of Massachusetts

To develop a list of potential interviewees, we reviewed the policy literature and identified the key groups of stakeholders relevant to the subject of BHI as listed above. Within each group, we relied on input from the [CEPAC Advisory Board](#) to identify key individuals and organizations to interview as part of our research process. When conducting interviews with initial contacts, we sought recommendations for additional regional and national experts to include as part of our assessment. Most of the practices interviewed represented more advanced levels of BHI, ranging from co-located practices with basic levels of collaboration to fully integrated care practices with close collaboration across care team members. The discussion that follows below is therefore focused on the challenges and potential opportunities for these practices as opposed to those with basic levels of care coordination and/or different locations for primary care and behavioral health services. We conducted 30 – 60 minute telephone interviews with each individual using a semi-structured guide. We attempted contact with a range of stakeholders within each New England state, though due to time limitations and scheduling challenges, were unable to interview all relevant stakeholders. To help ensure that key barriers and solutions were not left out of our assessment, we performed a scan of the existing policy literature to confirm our findings. The sections below summarize these conversations and distill key lessons or recommendations supported by a large majority of experts.

**9.1 Advancing Integration in New England: Barriers to and Opportunities for BHI**

Despite the desire of many to integrate behavioral health into primary care, significant barriers have been articulated by researchers and practitioners across the US.<sup>35,202,204,205</sup> We identified several areas in our discussions with key informants and review of the policy literature where improvements may be made to support BHI. Barriers and the potential solutions to overcome them can be grouped into the following categories:

- Cultural and historical influences
- Licensing and certification
- Technology, information sharing, and performance measurement
- Provider training and practice capacity
- Clinical operations, workflow, and spacing
- Reimbursement and payment policies

The barriers and potential solutions within each category are described below and summarized in Table 13 on page 87. The challenges and opportunities discussed below build on many of the issues introduced in Section 2.

### Cultural and Historical Influences

#### *Key barriers and opportunities:*

Primary care and behavioral health have historically functioned as two separate siloes of care. State policymakers in New England noted that the fragmentation of care has been upheld by separate funding streams for primary care and behavioral health services in the public sector. The carve-out payer environment has also reinforced the divide between care sectors at the practice level by delegating the responsibility for budgets, provider networks, and management of patient health information across separate entities. Stakeholders recognized the problem with carve-out strategies, but felt that this system is so entrenched that a shift to “carve-in” arrangements is highly unlikely.

The distinct practice cultures between primary and specialty behavioral health care also pose an ongoing challenge to BHI. PCPs are typically accustomed to seeing more patients per hour than behaviorists, and they incorporate more flexibility into their schedules to accommodate walk-in appointments for patients with immediate issues. Behavioral health practitioners typically have longer appointments (lasting 45 minutes to an hour or longer) and are less likely to be interrupted during patient visits to address other needs. Incorporating behaviorists on primary care teams requires redesigning workflows and defining a new culture for team-based care that may require significant training.

Key informants also noted that though significant strides have been made, societal stigma towards behavioral health treatment and conditions remains a barrier to BHI. There is a sense among stakeholders interviewed that integrating behavioral health into primary care helps reduce stigma by making behavioral health treatment a more embedded part of medicine, but outdated regulations intended to protect patients with behavioral health issues may be inadvertently reinforcing stigma by making it more difficult for these individuals to access comprehensive care.

To overcome cultural barriers, all key informants recognized support from senior leadership as one of the most important enabling factors to BHI. Clinical experts mentioned that frontline care team members typically understand the importance of BHI and its goals more clearly than practice leadership, which can delay progress and practice change. Practices where the CEOs, CFOs, CMOs, and/or Board of Directors committed to BHI were more likely to achieve consensus and advance integration from the beginning stages.

When hiring new team members to serve as behaviorists, experts emphasized the importance of tailoring job descriptions to attract the right person and skill set. Behaviorists in primary care may function more like a PCP in that they are gatekeepers – responsible for providing a quick assessment and triaging to the appropriate level of care. Job descriptions for integrated settings should therefore avoid reading like a standard medical description for counseling and psychotherapy and instead prioritize coordination skills, team-based care, and working in a fast-paced, primary care environment. The SAMHSA-HRSA CIHS developed core competencies for care team members working in integrated care settings (see Section 1.3) that may serve as a helpful starting point.

### Licensing and Certification

#### *Key barriers and opportunities:*

State and federal licensing and certification requirements are oft-cited barriers that hinder integration of services at the practice level. As previously mentioned, the federal and state systems that regulate integrated health systems are rarely integrated themselves, meaning that there is often poor alignment of processes, rules, and missions across agencies. It is not uncommon for practices attempting to co-locate physical and behavioral health services to require separate licenses from multiple government agencies or departments, which can be costly and administratively challenging, particularly for smaller practices. In some states, regulations may prevent co-location of services outright. For example, Massachusetts requires new or renovated facilities to have separate waiting rooms for behavioral health and primary care patients.<sup>205</sup> Recently the state has granted waivers to this requirement to support integration, but receiving a waiver can be subject to “an administrative lottery” and may take over a year to obtain. In Connecticut, the Department of Public Health recently approved legislation that reversed a long-standing rule that prevented behavioral health facilities from providing any service “off-site” in satellite physician offices or other health care settings. A multi-care facility license now allows behavioral health facilities to provide care in a variety of settings, removing a significant barrier to integration.<sup>206</sup>

Key informants agreed that licensing and certification standards need to keep pace with changes to primary care practice, and recognized the need to update licensing and certification policies that

hinder integration. For example, some experts recommended allowing discounts for professionals who certify as a care team, and creating an option for integrated practice groups to apply for a single license rather than acquiring separate licenses for each facility or practice, as typically required by regulation. Some states have introduced licensure requirements that actively promote integration. For instance, Massachusetts recently proposed legislation that would require hospitals and FQHCs to provide access to behavioral health services, either directly or through contracts, in order to be licensed in the state.<sup>215</sup> The state is also working to revise PCMH criteria to include BHI elements, including requirements for care managers to have training specific to the identification and coordination of behavioral health needs, as well as new screening requirements for behavioral conditions.<sup>215</sup>

## Technology and Information Sharing

### *Key barriers and opportunities:*

BHI depends on the ability of clinicians to collaborate and discuss patient information. Key informants all recognized EHRs as an essential tool, noting their role in driving communication, scheduling, performance monitoring, and patient follow-up. Practice experts did recognize several challenges to their implementation, however, including difficulty communicating with providers using different EHR systems and the inability to customize health record templates to meet unique practice needs as well as manage and monitor behavioral health input. Moreover, behavioral health providers are less likely to use EHRs due to more stringent privacy laws affecting the care of patients with substance use and mental illness disorders<sup>40</sup> as well as lacking financial incentives for behavioral health clinicians to adopt their use.<sup>41</sup>

The ability of EHRs to facilitate communication is challenged in part by patient confidentiality standards. HIPAA, though not designed to prevent appropriate communication across providers for purposes of integration, has been interpreted in some settings to impede BHI. Experts noted the need for more education and support to help practices understand the legal issues of sharing protected health information. Separate legislation that requires additional authorization to share mental health information or for substance use facilities to share patient information with primary care practices pose different challenges. These protection laws mean that practices often maintain mental health and physical health records separately, and that Behavioral Health Homes or other specialty mental health facilities do not communicate back to primary care providers when a patient has been seen within their practice. Primary care practices therefore may not be notified in the most vulnerable times of transition, including when a patient is discharged from a mental health facility. This lack of communication among primary care and specialty behavioral health organizations makes it difficult to know if duplicate services are being performed, and if adjustments need to be made to a patient's treatment plan.

To better facilitate communication between specialty mental health facilities and primary care practices, particularly in areas where existing EHR systems lack interoperability, some practices have relied on CHWs and patient navigators to identify when patients receive specialty mental health services and help support the coordination of services between primary care and Behavioral Health Homes. Patient navigators and CHWs are also being used to help link higher risk patients with community resources and provide follow-up and engagement outside of the primary care visit.

In practices with EHR systems, experts noted the value of EHRs to support data registry efforts and track how patients' needs are met through time. Experts emphasized the importance of adopting systems with embedded communication tools to help facilitate co-management of treatment plans and monitoring of outcomes. Experts also recommended that practices maintain behavioral and physical health notes in one record to the extent possible, citing situations where important behavioral health information was missed by PCPs in records that maintained mental health notes separately.

### Provider Training and Practice Capacity

#### *Key barriers and opportunities:*

Key informants from each New England state emphasized network capacity issues and noted that there is a shortage of primary care and behavioral health providers to meet the needs of the communities they serve. Even in states with adequate numbers of health care staff, primary care and behavioral health providers tend to be concentrated in certain areas and are not distributed to reflect geographic needs. This is particularly true in rural areas of the region, where it is difficult to recruit and retain clinicians.

Moreover, available primary care and behavioral health providers are rarely trained in integrated care. As discussed previously, psychologists, social workers, and psychiatrists are typically not trained in the primary care setting. PCPs, PAs, RNs, NPs, and other primary care team members may lack exposure to behavioral issues and may be uncomfortable managing behavioral health medications and treatment plans. Administrative staff in primary care settings may also lack familiarity with behavioral health billing and integrated care scheduling. Therefore, major re-training of staff is necessary to support BHI efforts and help each team member understand their scope of work and the goals and mission of integrated care. Some experts also noted pushback from primary care team members to expand the scope of their role in an area where resources and time are already limited. Research suggests that if PCPs performed all recommended screening and preventive services for all individuals in a patient panel it would take over 7 hours a day.<sup>208</sup> Primary care staff in particular feel pressure to adapt their practice to other ongoing reform efforts,

including medical homes, ACOs, and new quality and performance measures, all without significant increases to reimbursement.

Experts also noted that the shortage of specialty behavioral health providers impacts BHI in primary care settings. Insufficient referral sources for specialty behavioral health, and avoidance of specialty mental health services by individuals stigmatized by treatment in these settings suggests that patients with SMI or severe substance use disorders are more likely to access behavioral health services in primary care settings, which may lack the resources to respond to these patient needs. Some primary care practices also noted that it can take over a month to secure an appointment with a specialist for more complex patients, placing additional strains on BHI systems.

Specialized integrated care training can help prepare primary care staff and practice leadership for the unique BHI environment. Though not yet a mainstream component of medical or psychology training, some programs exist both in the region and nationally. For example, the [Center for Integrated Care](#) at University of Massachusetts Medical School provides specialized integration training for a range of perspectives, including for behavioral health providers transitioning from specialty practice to the primary care setting, for care managers working in medical homes and other integrated settings, and for administrators and physicians hoping to establish integrated practices. Experts also called for more residency and training programs for behavioral health providers in primary care settings, and for more education on how to adapt traditional behavioral health tools that are crafted for longer appointment structures to primary care practice. Some health systems such as Intermountain Health Care and Cherokee Health systems have established their own internal training systems from which they recruit behavioral health care managers and other team members.

As a response to issues of access to behavioral health providers, some states have developed innovative solutions, particularly in the area of child psychiatry. For example, the Massachusetts Child Psychiatry Access Project has established consultation “hubs” across the state that allow pediatricians serving children and adolescents with behavioral health conditions to call centers staffed by behavioral health specialists in order to receive guidance and clinical advice from psychiatrists in real time. The initiative is funded through the state, but available to all children in Massachusetts. The program has been adapted elsewhere in New England, including the Access Mental Health program in Connecticut. Connecticut is also developing a central database and clearinghouse of providers accepting new patients to help individuals access services, given issues with network capacity. In Vermont, some health systems have moved towards establishing “medical neighborhoods” to help address network capacity issues. In this model, medical home primary care practices refer patients with more complex behavioral health needs to specialty organizations to stabilize patients, after which they are transferred back to primary care practices for ongoing management to help improve efficiency and ensure that patients are being treated in the care setting most appropriate to their needs. Other states are investing in community hospitals

to improve system capacity for behavioral health by partnering FQHCs with area hospitals to foster greater collaboration across providers.

Some states, particularly those with rural populations, are also pursuing telemedicine to link patients in areas with staffing shortages to providers in other areas. In several practices in the region, psychiatrists serve in a consultative capacity due to shortages that prevent them from being fully embedded on care teams. Under these models, psychiatrists provide consultation, often through telemedicine, to behaviorists and PCPs to inform initial treatment decisions, particularly if medication is required. In special circumstances psychiatrists will meet with patients in-person once treatment has been initiated.

### Clinical Operations, Workflow and Space

#### *Key barriers and opportunities:*

One of the key challenges to integrating behavioral health and primary care services is knowing how to staff care teams and introduce a new level of flexibility into workflows to facilitate integration. In integrated settings, time needs to be allocated for team members to discuss cases and coordinate treatment plans, provide real-time consulting when problems are identified, and for “warm hand-offs”, when behaviorists enter primary care appointments to introduce themselves to patients, explain services, and take care of any urgent concerns immediately. Some clinical experts noted the challenge of knowing the optimal ratio of behaviorists to other primary care staff to address population needs, as well as the difficulty in restructuring scheduling and clinical operations to allow for the flexibility required by BHI. Office space also plays a pivotal role in a practice’s ability to adopt BHI, since many facilities are not arranged to allow all physical and behavioral health practitioners to be located on one floor or even in the same building, hindering the ability for “warm hand-offs” or real-time consulting across team members.

Some primary care practices noted problems with no-show rates when, due to billing limitations for same-day visits, patients with an identified behavioral health need would schedule a future appointment with a behavioral health provider and never return for the visit. No-shows are especially detrimental, as not only is the patient with a scheduled appointment potentially missing out on needed services, but the wasted appointment signifies lost access for other patients in the community.

Experts emphasized the importance of shifting towards a population-based approach to health care delivery, whereby behavioral services are a core feature of primary care services for all patients. More advanced integration models screen every patient for anxiety and depression during their annual visit. In these practices, algorithms are used that automatically refer every patient who screens positive for depression and/or anxiety to a member of the behavioral health team, usually

in the same visit. Other referrals are based on physician selection. In some practices like Cherokee Health Systems, behavioral consults are automatically assigned to certain preventive appointments like well-child visits and high-risk prenatal services, since they provide important opportunities to provide education and anticipatory or proactive services.

In terms of adapting clinical workflows and scheduling to accommodate for greater collaboration, some experts recommended reserving every other appointment time slot for provider-to-provider consultation. Other practices have instituted no closed-door policies to help foster a culture of collaboration and encourage team members to interrupt appointments when issues are identified. Cherokee Health Systems has adopted an innovative approach in which behavioral health consultants carry a portable laptop that allows them to move throughout exam and consultation rooms to address patient issues as they arise. RNs are used to carefully manage workflow and allocate space to ensure that appointments run on schedule. If PCPs fall behind in their schedule, behaviorists may initiate appointments with patients and provide some primary care services to keep them from waiting. The optimal number of behavioral health team members will depend on each practice's unique patient case mix and how broadly the practice defines the scope of behavioral health care. Some experts mentioned that, as a general rule, behavioral health staff should be available 2-4 hours weekly for every 1,000 patients in typical primary care practices.<sup>195</sup> Others mentioned hiring one behaviorist for every 3-4 PCPs, depending on the size of the practice. The AIMS Center at the University of Washington has also developed a staffing formula for diverse primary-care settings based on unique needs of the population being treated, which is discussed in section 8.2 of this report.

Clinical experts recommended hiring behaviorists that are fully embedded on the care team, rather than leasing individuals from other networks. Contracted workers may lack the organizational vision for BHI that is part of staff training, and they may not be seen as full team members by other practitioners even if there every day. Practices took many different approaches to staffing depending on the practice setting and unique patient case mix, but often included LCSWs or licensed psychologists to serve as care managers, PCPs, RNs, and NPs, and CHWs or care navigators. As in the AIMS/Collaborative Care model, psychiatrists were often available on a consultant basis to provide guidance for more complex cases or to serve as a referral for patients requiring long-term care. Behavioral health team members should participate in "team huddles" and be included in decisions about workflow. The structure and timing of team meetings also varied according to the unique patient needs at every practice, but ranged from daily for practices providing outpatient substance use treatment to monthly. Key informants also underscored the importance of not only hiring new line staff to integrate care, but also of establishing new leadership positions to oversee the transition to integration. Practices tend to underestimate the level of expertise and time required to establish new workflows and clinical processes to facilitate BHI, so hiring new directors of integration can be paramount.

Experts also emphasized the importance of “warm hand-offs” between care team members to reduce the number of no-shows, particularly for more complex cases. Allowing time during appointments for behaviorists to introduce themselves to patients, explain services, and take care of any urgent concerns immediately has made it more likely for patients to return to appointments for ongoing management. In some practices with fewer resources, “warm hand-offs” are reserved for critical cases.

To overcome scheduling barriers, some FQHCs in the region have turned to open access appointment systems, whereby appointments are not scheduled in advance, and patients are seen on a first-come, first-served basis. In these settings, appointments are structured in 20-30 minute intervals during which a primary care team member assesses a patient’s needs and triages to the appropriate level of care. Follow-up visits may be made with a behaviorist or other team member as appropriate. A certain number of appointments are held for patients that pre-book follow-up appointments with a PCP or behaviorist.

## Reimbursement and Payment Policies

### *Key barriers and opportunities:*

Experts were nearly unanimous in stating that low payment rates, FFS incentives, and complex billing rules are among the most pressing challenges to sustaining BHI. The initial investment required to establish an integrated system is significant, which may involve hiring and onboarding new staff, redesigning work flows, retraining existing staff, and establishing shared information and patient tracking systems. Therefore, working through billing issues and adopting value-based payment structures that better support the work of BHI and shift incentives towards care management and coordination are crucial to sustaining integrated efforts.

As previously discussed, FFS reimbursement makes it difficult to receive payment for activities core to BHI, including care management and collaboration across providers, and places limitations on which clinicians can provide services. Experts noted significant confusion regarding the unique billing rules across payers, including same-day billing rules and licensure requirements for HBAI billing codes that often differ across care settings. Clinicians also sought greater clarity on which codes can be used for case management services provided when a patient is not present. Experts noted only being able to bill for activities like “warm hand-offs” when comprehensive intakes are also provided, which may not be required clinically yet are performed since clinicians need to be reimbursed for their time. Coding challenges may also affect the level of reimbursement practices receive for BHI. Clinical experts noted that physical health clinicians typically bill using evaluation and management (E&M) or psychiatric codes, whereas behavioral health clinicians typically rely on HBAI codes that receive lower reimbursement rates.

Public and private health plans are increasingly pursuing value-based contracts to shift reimbursement away from more rigid FFS structures. Payment reform efforts in the region have often included elements of capitation, whereby practices receive a PMPM amount over a base reimbursement rate (typically based on the previous year's FFS billings) to help support practices in establishing integrated care. The PMPM "bump" has been used to fund care coordination, case management, and other practice enhancements. Some states, like Massachusetts, are pursuing payment reform models that tie supplemental payments directly to BHI and the level of behavioral health services provided in primary care. Some health plans have turned to other reimbursement mechanisms to incentivize integration, including shared savings models, bonus payments based on performance, and episode-based reimbursement, in which providers receive a single payment for all services a patient receives for a specific condition over a defined period.<sup>209</sup> Examples of some regional payment reform efforts are described in Table 12 on page 84.

Even where there is widespread support for value-based reimbursement, both payers and providers have noted various challenges to transitioning away from FFS. First, some payers mentioned that introducing global payment structures to support integration can be a non-starter in organizations where they represent a small proportion (20% or less) of the market share of the patient population. Similarly, provider groups may find it difficult to fully invest in integrated care for a minority of patients in a global payment structure while not getting paid at all for the same services rendered to FFS patients. Another oft-cited challenge to shifting to global payment structures is establishing a monthly payment that is cost saving and provides an appropriate level of revenue for practices. Some of the architects of state payment reform initiatives in New England mentioned underestimating the time it would take for practices to observe a return on investment for PCMH integration efforts, leading some practices to revert back to FFS before change could be realized. Anecdotal experience revealed that it could take practices 2-5 years to achieve cost neutrality, given the significant initial investment involved with primary care transformation and the time it takes to standardize integration, which conflicts with state budget timelines.

Other experts noted that in some cases capitated rates were likely set too high, particularly in those practices with few high utilizers. Key informants called for more sophisticated, objective risk-adjustment algorithms to more appropriately establish rates and allocate resources. Experts also cautioned that capitation introduces a level of opacity to reimbursement and makes it more difficult to monitor which services are being delivered and have value. Though global payments introduce a level of flexibility for practices to better provide coordinated, comprehensive services, some experts feared that there is a financial mismatch between which services are being paid for and which are actually being utilized when setting rates. When rolling out supplemental capitated payments, payers acknowledged uncertainty around what services are already being paid for through FFS to be able to make accurate valuations of the supplemental care being provided. Payers called for greater understanding of what services individuals are accessing in primary care and what level of integration is achieved to help determine the true cost of implementing and managing BHI.

For practices attempting new delivery and payment models such as ACOs and PCMHs, experts noted the challenge of adapting existing models to support integration. Many organizations are still in the process of transforming practices to meet the reporting and infrastructural changes needed for an ACO or PCMH, and have not been able to advance to include specific incentives for BHI. Experts anecdotally shared that many practices participating in state payment reform efforts had yet to establish case management services within six months due to the amount of infrastructure changes needed to meet reporting requirements and be eligible for payment.

As reimbursement is increasingly linked to performance, experts also called for greater consensus among payers and providers on key outcome measures for BHI and how performance should be evaluated. Health plans often enter ACO contracts with their own set of performance standards and expectations that can make aligning efforts around integration challenging. Moreover, measurement options are limited for evaluating clinician behavior and adherence to different models for BHI. Some tools exist, for example the VA’s Primary Care Behavioral Health Provider Adherence Questionnaire, though they may not be relevant to all care settings or models of BHI.

Though recognizing the need to monitor outcomes on BHI, patient advocates had concerns that some performance measures could create perverse incentives. For example, if practices are rewarded for scheduling physical and mental health visits on the same day, some patients feared that this could lead to longer wait times for appointments or being rushed through appointments for the sole purpose of meeting the same-day standard.

**Table 12. Select Payment Reform Efforts in New England**

<p><b>Massachusetts Primary Care Payment Reform Initiative (PCPRI)<sup>210</sup></b></p>	<p>As a response to 2012 legislation requiring the development of alternative payment methodologies, MassHealth has launched a payment reform initiative designed to improve the integration of behavioral health and primary care by developing the PCMH model and granting PCPs more flexibility and resources to deliver comprehensive services. The program involves a three-pronged payment structure:</p> <ul style="list-style-type: none"> <li>• Risk-adjusted capitated payment for primary care services (based on previous year’s billings). May include some behavioral health services.</li> <li>• Annual quality incentive payment for performance on specific measures</li> <li>• Shared savings from reductions in non-primary care spending (e.g., hospital and specialist services) for primary care providers</li> </ul> <p>Participating practices receive a Comprehensive Primary Care Payment based on the level of BHI provided:</p> <ul style="list-style-type: none"> <li>• Tier 1: no requirement for behavioral health services to be provided, but care coordination is expected</li> <li>• Tier 2: practice meets minimum BHI services, including diagnostic evaluations, depression screening, individual and group therapy, etc. A full-time behavioral health provider is on-site with ability to schedule appointments within 14 days of request.</li> </ul>
--	---

	<ul style="list-style-type: none"> <li>• Tier 3: practice meets higher level of BHI services, including medication management and psychiatric testing. On-site psychiatrist is part of care team that has access to behavioral health record for each patient.</li> </ul> <p>Payments for higher tiers are coordinated with behavioral health carve-outs. 70% of participating programs chose Tier 1 in first year.</p>
<p><b>Blue Cross Blue Shield of Massachusetts Alternative Quality Contract (AQC)<sup>211</sup></b></p>	<p>Launched in 2009, BCBS MA introduced a new payment model to reduce health care spending while driving quality. A goal of the AQC is to support integration by granting PCPs more flexibility to provide coordinated services and restructure incentives to reward health outcomes. Core features of the model include:</p> <ul style="list-style-type: none"> <li>• Risk-adjusted capitated payment based on historical spending for primary care, specialty care, hospital care, ancillary services, behavioral health, and pharmacy expenses. Annual inflation rates were established upfront for each year of the contract.</li> <li>• Shared savings and shared risks</li> <li>• Performance bonuses based on nationally validated standards for inpatient and outpatient care, including chronic care processes and outcomes, acute and preventive care processes, and patient experience</li> <li>• BCBS MA provides data and reports to support participant’s success in managing budgets and improving outcomes.</li> </ul>
<p><b>Vermont Blueprint for Health<sup>52, 96</sup></b></p>	<p>A state-led initiative codified into law in 2006 with the goal of integrating services for all patients while improving care quality and controlling health care costs. Vermont’s Blueprint for Health is a multi-payer program that supports the development of PCMHs and community health teams that include care integration coordinators, behavioral health specialists, CHWs, and other core primary care team members to manage and coordinate services. Funding for the model involves the following key features:</p> <ul style="list-style-type: none"> <li>• FFS plus a supplemental PMPM payment tied to NCQA scores</li> <li>• Cost of community health teams is split across all participating payers (which included Medicaid, Medicare, and three commercial plans in 2014). Costs are split evenly, with some adjustments made for market share. In 2011 each community health team had an annual cost of \$350,000.</li> </ul>

Key informants also noted that higher co-payments for behavioral health services by Medicare and some commercial insurers serve as an obstacle to BHI. Historically, patients have incurred higher co-payments for visits to behavioral specialists than for visits to primary care providers, but as practices shift towards integrated care and behaviorists are embedded on care teams, some experts feel that the distinction no longer makes sense. Particularly for safety net patients, an additional co-payment of \$40 - \$50 (Medicare rates) to see a psychologist or social worker makes it unlikely that patients will opt to see behavioral health and primary care providers during the same visit. Health plans may also have limited provider networks that can impede BHI.

Reimbursement for behavioral health service provided via telemedicine may also be limited. As more states turn to telemedicine as a solution to workforce shortages, key informants mentioned the need for greater consistency in how telemedicine is reimbursed across payers. Some payers will only reimburse for a psychiatrist’s time when providing consultative services to a primary care

provider, which may discourage the use of this technology among other primary care team members.<sup>212</sup>

The shift towards value-based payment is ongoing and FFS will likely remain an important aspect of BHI sustainability in the short-term. Experts therefore noted the importance of making HBAI codes available in states where they currently are not to allow for greater coordination across providers. In cases where shared savings models are utilized, health plans emphasized the importance of incorporating both “upside” *and* “downside” risk, meaning that providers accept some accountability for costs that exceed targets or if they fail to meet certain quality standards, or there will be little incentive to continually improve. Other experts noted that performance measures for bonus payments should also include explicit standards for integration, such as depression and anxiety screening, to further incentivize BHI.

In terms of differential co-payments for primary and behavioral health care, experts suggested that health plans move away from linking copayments to the type of professional delivering the service and rather to the service provided. Patient copayments for visits to all primary care team members should be the same if these providers are practicing in the same setting so as not to provide a deterrent to patients seeking behavioral health services in primary care. Experts recognized that doing so may be a major administrative challenge to implement and would require potentially significant changes from health plans.

## Summary

Significant efforts are underway in New England to integrate behavioral health and primary care. Several factors conspire to make the integration of primary and behavioral health care challenging, including distinct practice cultures between primary and behavioral health care; siloed funding streams and regulations for medical and behavioral health that reinforce fragmentation at the practice level; limited data sharing and use of EHRs; a shortage of primary care and behavioral health providers, particularly with training in integrated settings; and the continuation of FFS reimbursement, which fails to incentivize collaboration across team members or reimburse providers for services core to integration. Although the challenges to BHI are ongoing, policymakers, providers, and health plans are pursuing innovative approaches to facilitate the delivery of comprehensive, person-centered care in primary care settings. An overview of the key barriers and opportunities for BHI in New England discussed above are summarized in Table 13 on the following page.

**Table 13. Summary of Major Barriers to and Opportunities for BHI in New England**

Category	Specific Issues
Cultural and Historical Influences	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Separate silos for behavioral health and physical health – both in terms of service delivery and financing</li> <li>• Distinct practice cultures between primary and specialty behavioral health care reinforced by differences in training, licensing, and certification for primary care, mental health, and substance use</li> <li>• Ongoing societal stigma related to mental health and substance use conditions</li> </ul>
	<p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Support from senior leadership to gain consensus and advance BHI beyond beginning stages</li> <li>• Tailored job descriptions to attract candidates with the vision and skill set for BHI</li> </ul>
Licensing and Certification	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Requirements that practices acquire separate licenses from multiple government agencies or departments to co-locate services</li> <li>• Legislation that poses barriers to co-location, such as requirements that practices have separate waiting rooms for behavioral health and primary care patients</li> </ul>
	<p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Licensure amendments that make access to BHI (through contract or direct service) a requirement for licensure</li> </ul>
Technology/ information sharing	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Challenges related to limited data sharing via EHRs, which are preferred but are not as widely used by behavioral health providers as by physical health providers</li> <li>• Interoperability of different EHR systems and the inability to customize health record templates to meet unique practice needs as well as manage and monitor behavioral health input</li> <li>• Confidentiality laws that are more restrictive for behavioral health (particularly for substance use) than for physical health</li> <li>• Fragmented communication among providers of primary care, mental health, and substance use services</li> </ul>
	<p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Use of CHWs or patient navigators to identify when patients receive specialty mental health services and help support coordination of services between primary care and specialty behavioral health providers</li> <li>• EHR systems that embed communication tools and directly link to data registries to monitor patient outcomes</li> </ul>

Category	Specific Issues
Provider training and capacity	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Limited training of primary care physicians in behavioral health conditions and of behavioral health providers in physical health conditions</li> <li>• Shortage of primary care and behavioral health providers to meet the needs of the communities they serve, as well as substantial variation in provider supply across the region</li> <li>• Scope of practice concerns, particularly in primary care where resources and time are already limited</li> <li>• Lack of access to specialty behavioral health providers for patients with severe behavioral health needs, which places additional strains on BHI in primary care</li> </ul> <p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Specialized integrated care training that helps primary care staff and practice leadership for the unique BHI environment</li> <li>• Development of consultation “hubs” that allow primary care providers serving patients with behavioral health conditions to connect with call centers staffed by behavioral health specialists to provide guidance and clinical advice in real time</li> <li>• Development of central databases and clearinghouses of providers accepting new patients to help individuals access behavioral health services</li> <li>• Use of telemedicine to link patients in areas with staffing shortages to providers in other areas</li> </ul>
Clinical operations, workflow, and space	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Challenges related to adapting clinical workflows and scheduling to accommodate greater levels of flexibility and real-time collaboration</li> <li>• Lack of space to place physical and behavioral health team members on same floor or same building</li> </ul> <p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Population-based strategies that screen all patients for depression and anxiety using validated screening tools and protocols that triage patients with positive screens to appropriate levels of care</li> <li>• Adoption of flexible scheduling approaches that reserve blocks of time for provider-to-provider consultation or use of open-access booking that reduces the number of no-shows for visits</li> <li>• Fully embedding behaviorists on the care team by hiring full-time staff that are included in all team meetings and co-manage treatment plans with other primary care team members</li> </ul>

Category	Specific Issues
Reimbursement and payment	<p><b>Barriers:</b></p> <ul style="list-style-type: none"> <li>• Payment that has historically rewarded volume through fee-for-service payments rather than outcomes through capitated payments and shared risk/shared savings models</li> <li>• Limitations on billing including: <ul style="list-style-type: none"> <li>○ Who can bill for services</li> <li>○ Requirements that services be delivered face-to-face to be eligible for payment</li> <li>○ Lower reimbursement for health and behavioral assessment/intervention (HBAI) codes typically used by non-physician providers than for evaluation and management (E&amp;M) codes typically used by physicians</li> <li>○ Inability to bill for care coordination and communication activities</li> </ul> </li> <li>• Challenges related to establishing global payment rates that are cost-saving but provide an appropriate level of revenue to practices</li> <li>• Challenges related to adapting existing delivery and payment models such as ACOs and PCMHs to support BHI</li> <li>• Lack of consensus around outcome measures for BHI and how performance should be evaluated to support reimbursement efforts tied to performance</li> </ul> <p><b>Potential Opportunities:</b></p> <ul style="list-style-type: none"> <li>• Alternative payment models such as capitation, and/or provide incentives to integrate care such as shared savings and/or shared risk; capitation payments should be risk-adjusted</li> <li>• Enhanced capitation payments for care management services and collaborative care delivered in integrated care settings</li> <li>• Payments for psychiatry consults to primary care by phone</li> <li>• Use of performance incentives to reward clinical improvement and have withholds for inappropriate care</li> <li>• Allowances for same-day billing of physical and mental health services when provided by two separate providers</li> <li>• Increased reimbursement of evidence-based practices</li> <li>• Increased payment for non-physician providers</li> <li>• Reduction in limitations to the types of providers who can bill for certain services</li> </ul>

This is the first review of this topic by CEPAC.

# APPENDICES

# Appendix A. Key National Models for BHI

## Summary of Select National BHI Programs

Program	Overview of Key Features
<p><b>Cherokee Health Systems (Behavioral Health Consults)</b></p>	<p>Cherokee Health Systems is a network of FQHCs and community mental health organizations in Tennessee that operates over 50 clinic sites throughout the state. Core features of the model include:</p> <ul style="list-style-type: none"> <li>• <b>Screening:</b> Primary care team members screen every patient for behavioral health conditions to triage care accordingly and identify treatment and care support needs of each patient.</li> <li>• <b>Team-based care:</b> Generalist Behavioral Health Consultants (BHCs) are typically licensed psychologists and are fully embedded on the care team and co-manage patients found to have behavioral health conditions. BHCs are also a standard part of all well-child visits and prenatal care appointments to address psychosocial challenges, provide screening, and provide patient education and prevention.</li> <li>• <b>Integrated workflow:</b> BHCs provide rapid access to behavioral health treatment on the same day – often during the same patient visit. Consultant psychiatrists are also available to provide specialized consultative services to PCPs and BHCs for complex cases. A robust orientation is provided to all members of the care team, including analytical and administrative staff, to provide an overview of the mission of integration and scope of each person’s position within the care team. BHCs receive additional specialized training on integrated care.</li> <li>• <b>Shared information system:</b> Members of the care team share access to the same EHR that facilitates information exchange across practitioners.</li> <li>• <b>Systematic measurement:</b> EHRs are used to track patient outcomes, share notes, and obtain data on core health outcomes to track improvements and adjust patient care as needed.</li> </ul> <p>Cherokee Health Systems has additionally trained numerous other health systems on its model through its Primary Behavioral Health Integration Academy.</p>
<p><b>IMPACT Model/Collaborative Care</b></p>	<p>Developed by the University of Washington, Collaborative Care, or the IMPACT model, integrates treatment for a range of mood and anxiety disorders, as well as broader mental health conditions into primary care settings. The AIMS Center based at the University of Washington focuses on the implementation of Collaborative Care and has worked with hundreds of practices nationally and internationally to apply and adapt the model.</p> <p>Core features of the IMPACT model include:</p> <ul style="list-style-type: none"> <li>• <b>Screening:</b> Care team members screen patients for depression using validated screening tools, such as the PHQ-9, a nine item questionnaire.</li> </ul>

Program	Overview of Key Features
	<ul style="list-style-type: none"> <li>• <b>Team-based care:</b> Primary care and behavioral health providers collaborate using shared treatment plans that are individualized to meet each patient’s unique circumstances and goals. Core members of the team include a primary care physician (PCP), care manager, and psychiatric consultant. The care managers may be nurses, social workers, psychologists, or other trained health professionals.</li> <li>• <b>Integrated Workflows:</b> Care managers support PCPs in coordinating treatment, providing brief counseling, providing proactive follow-up, notifying PCPs when outcomes are not improving, supporting medication management, and communicating any treatment changes to psychiatric consultant team members. Psychiatric consultants support PCPs and care managers when diagnosing patients, and in designing treatment plans and adjustments when patients are not experiencing improvements (i.e., stepped care). Psychiatric consultants may work directly with patients in complex situations.</li> <li>• <b>Systematic Measurement:</b> Patient progress is tracked and regularly monitored in a central registry, and workflow adjusted so more resources can be allocated to patients who are not improving as expected.</li> </ul>
<p><b>Intermountain Healthcare Mental Health Integration Program</b></p>	<p>Intermountain Healthcare is an integrated health system of over 20 hospitals and 200 outpatient clinics serving the metropolitan area of Salt Lake City, Utah. The health system built on existing institutional structures for coordinated care to integrate primary care and behavioral health services. Features of this model are being applied to health systems nationally, including in Maine, Mississippi, New Hampshire, and Oregon.</p> <p>Core features of the model include:</p> <ul style="list-style-type: none"> <li>• <b>Screening:</b> All patients receive a comprehensive mental health assessment and are screened for depression, anxiety, and other behavioral health concerns using validated screening tools.</li> <li>• <b>Team-based care:</b> Mental health practitioners are embedded with the primary care team to co-manage care and may include psychiatrists, nurse practitioners, social workers, psychologists, peer specialists, or other professionals. Families are also considered part of the care team and included in treatment plans.</li> <li>• <b>Integrated workflows:</b> All members of the care team are housed within the same facility to facilitate seamless care transitions. Mental health practitioners rotate through clinics and are assigned in blocks of hours based on the unique patient mix at each clinic. For example, practices with more complex caseloads may have a rotating psychiatrist to handle appointments for a day a week, whereas practices with more mild-to-moderate cases may use psychiatric specialists for less time each week. Extensive training is provided to all team members on the goals and features of integration and each individual’s role within the model and care team.</li> <li>• <b>Shared information-systems:</b> A secure, central health information exchange is available to all team members to track and upload patient data, communicate, coordinate treatment plans, and measure patient outcomes.</li> </ul>

Program	Overview of Key Features
	<ul style="list-style-type: none"> <li>• <b>Systematic measurement:</b> A core set of measurement tools are used to document patient outcomes, assess the allocation of resources, and build consensus around integration needs.</li> <li>• <b>Engagement with broader community:</b> Intermountain Healthcare also establishes formal relationships with community resources to refer patients to broader social supports to reinforce treatment plans.</li> </ul>
<p><b>Department of Veterans Affairs (VA)</b></p>	<p>The VA integration program built on a strong existing infrastructure to implement a national strategy for BHI that focuses exclusively on SMI and depression. The program involves several individual projects that are coordinated but are individualized to each site's unique needs. Core features of the program include:</p> <ul style="list-style-type: none"> <li>• <b>Screening:</b> PCPs provide universal screening of depression and PTSD. Patients with positive screens are assessed for behavioral health needs using structured protocols performed by care managers.</li> <li>• <b>Team-based care:</b> Depression care managers are included on the primary care team and make recommendations to the PCP about treatment, provide proactive patient follow-up, and communicate with consultant psychiatric specialists when problems arise. Case managers are typically nurses or social workers.</li> <li>• <b>Integrated Workflows:</b> Care managers are supported by formal review and consultation with mental health specialists, who also see more complex patient cases as needed. Mental health and primary care team members are co-located and share responsibility for treatment development, monitoring, and ongoing management.</li> <li>• <b>Shared information system:</b> EHRs are used to facilitate provider communication, report data, and provide point-of-care decision support.</li> <li>• <b>Systematic Measurement:</b> A standard set of performance measures is used to track patient outcomes and improvements.</li> </ul>

## Appendix B. Patient Confidentiality Legislation in New England

Connecticut	<p><a href="#">CT ST § 52-146c</a>: A patient or patient’s authorized representative must provide consent for disclosure of information provide din any communication between psychologist and patient.</p> <p><a href="#">52-146f</a>: Communications may be disclosed without authorization under several conditions, including sharing of information to other persons engaged in the diagnosis or treatment of the patient or transferred to another mental health facility if the psychiatrist sees it as necessary for diagnosis or treatment. The patient must be informed that the information will be disclosed.</p>
Maine	<p><a href="#">ME R REV 503</a>: The patient may refuse to allow disclosure of confidential communications among the patient, physician, psychotherapist, and other people involved in the diagnosis or treatment.</p> <p><a href="#">LD534 An Act To Improve Care Coordination for Persons with Mental Illness</a>: Authorization for disclosure is not required for information shared within the office, practice, or organizational affiliate of the provider or health care facility.</p>
Massachusetts	<p><a href="#">MA Title XVI Chapter 112 Section 129A</a>: All communications between licensed psychologist and individuals with whom psychologist engages in practice of psychology are confidential</p>
New Hampshire	<p><a href="#">189:2 Use and Disclosure of Protected Health Information; Health Information Exchange</a>: Health care providers may transmit patient health information through the state’s health information organization. Information can be accessed only by a health care provider for treatment, care coordination, and quality assurance, or by a legal representative. Patients must be given the opportunity to opt out of having personal information such as a name or address shared with protected health information.</p> <p><a href="#">NH ST § 332-I:2</a>: Providers cannot share confidential communications or information without the patient’s consent, unless as required by law or to protect the patient or public interest.</p> <p><a href="#">Rule 503. Patient's Privilege</a>: Interactions between patients and state certified psychologists or pastoral counselors are confidential, and no psychologist or pastoral counselor should be required to disclose information without consent of the patient.</p> <p><a href="#">Chapter 330-A Mental Health Practice Section 330-A:32</a>: Interactions between patients and licensed state mental health providers are confidential, and no psychologist or pastoral counselor should be required to disclose information without consent of the patient.</p>
Rhode Island	<p><a href="#">RI Gen L § 23-17-19.1 (2012)</a>: State-licensed health care facilities must ensure patient privacy and confidentiality. All records related to a patient’s treatment should be kept private. Confidentiality does not prevent sharing of information between providers for the purposes of patient care.</p> <p><a href="#">§ 40.1-5-26 Disclosure of confidential information and records</a>: All information and records created during provision of mental health services cannot be shared without consent of the patient. Information sharing between qualified medical and mental health professionals that pertains to the patient’s care is allowed without patient consent. Consent must be obtained before sharing information with professionals outside of the facility where the patient is being treated.</p>
Vermont	<p><a href="#">12 V.S.A. § 1612</a>: Providers, including mental health professionals, are not able to disclose any information obtained while caring for a patient in a professional capacity unless the patient provides consent.</p>

# Appendix C. Sample Worksheets for Practice-Level Expenses Associated with BHI

## A. Start-Up Expenses

**Table 1 - Start-up expenditure data (prior to baseline)**

Practice Number:  to

Start-up period from Calendar Month and Year (MM/DD/YYYY):  to

	Total # of staff FTEs	Total hours devoted per staff category (over entire start-up period)	Average monthly Salary per 1 FTE	Average monthly Benefits per 1 FTE	Did you hire any new staff specifically for the intervention during the start-up study period? (if yes, specify FTE and start-up month)	New staff FTE	New staff start date	Notes?
<b>Section A1. Direct Staff Start-up Time</b>								
<b>Training</b>								
Clinicians								
PA								
Health Coach								
Behavioral Health Counselor								
Medical Assistant								
Front Desk								
Care Coordinator-RN								
Biller								
Referrals Coordinator								
<b>Section A2. Indirect Staff Start-up (Administrative)</b>								
Practice Administrator								
Other (please list staff category; use lines below)								
Medical Director/PI								
CFO								
COO or program personnel								
CEO								
MA Supervisor								
Front Desk Supervisor								
Billing Supervisor								
<b>Section B. Non-recurrent Start-up Expenditures (non-staff)</b>								
Space purchases (construction of health coaching rooms)	Estimated cost (\$)							
Computer hardware and any equipment purchases								
Computer software purchases								
Purchase of rights for an tool, instrument or measure								
Travel and transportation								
Other Asset purchases								
<b>Section C. Overhead Start-up Expenditures (non-staff)</b>								
Building and occupancy lease/rental during startup	Expenditure on all overhead items for the period (\$)		Average % of item devoted to ACT project					
Equipment lease/rental during startup								
Insurance (NOT malpractice) & finance fees								
Electronic software subscription fees								
Phone and utilities								
Administrative supplies and services								
Other expenses:								

Notes:

**Table 1D - Development expenditure data (prior to baseline)**

Practice Number:

Start-up period from Calendar Month and Year (MM/DD/YYYY):

0	to	
---	----	--

	Total # of staff FTEs	Total hours devoted per staff category (over entire start-up period)	Average monthly Salary per 1 FTE	Average monthly Benefits per 1 FTE
<b>Section A. Staff Development Time</b>				
<b>Staff Meetings with Community Reach</b>				
Practice Administrator			\$0.00	\$0.00
Medical Director/PI			\$0.00	\$0.00
Health Coach			\$0.00	\$0.00
Behavioral Health Counselor			\$0.00	\$0.00
<b>Development of Program Activities</b>				
Practice Administrator			\$0.00	\$0.00
Health Coach			\$0.00	\$0.00
Medical Director/PI			\$0.00	\$0.00
<b>Develop Workflow and Process Diagrams</b>				
Medical Director/PI			\$0.00	\$0.00
Practice Administrator			\$0.00	\$0.00
<b>Tool Development</b>				
Health Coach			\$0.00	\$0.00
Practice Administrator			\$0.00	\$0.00
<b>Website Redesign</b>				
Practice Administrator			\$0.00	\$0.00
Medical Director/PI			\$0.00	\$0.00
<b>Administrative and Legal Activities</b>				
Practice Administrator			\$0.00	\$0.00
Westminster Medical Director/PI			\$0.00	\$0.00
Clinicians			\$0.00	\$0.00
Health Coach			\$0.00	\$0.00

Estimated cost (\$)

**Section B. Non-recurrent Development Expenditures (non-staff)**

Travel and transportation	\$0.00
Other purchases	\$0.00

Expenditure on all overhead items for the period (\$)      Average % of item devoted to ACT project

**Section C. Overhead Development Expenditures (non-staff)**

Building and occupancy lease/rental during startup	\$0.00	0.0%
Equipment lease/rental during startup	\$0.00	0.0%
Insurance (NOT malpractice) & finance fees	\$0.00	0.0%
Electronic software subscription fees	\$0.00	0.0%
Phone and utilities	\$0.00	0.0%
Administrative supplies and services	\$0.00	0.0%
Other expenses:	\$0.00	0.0%

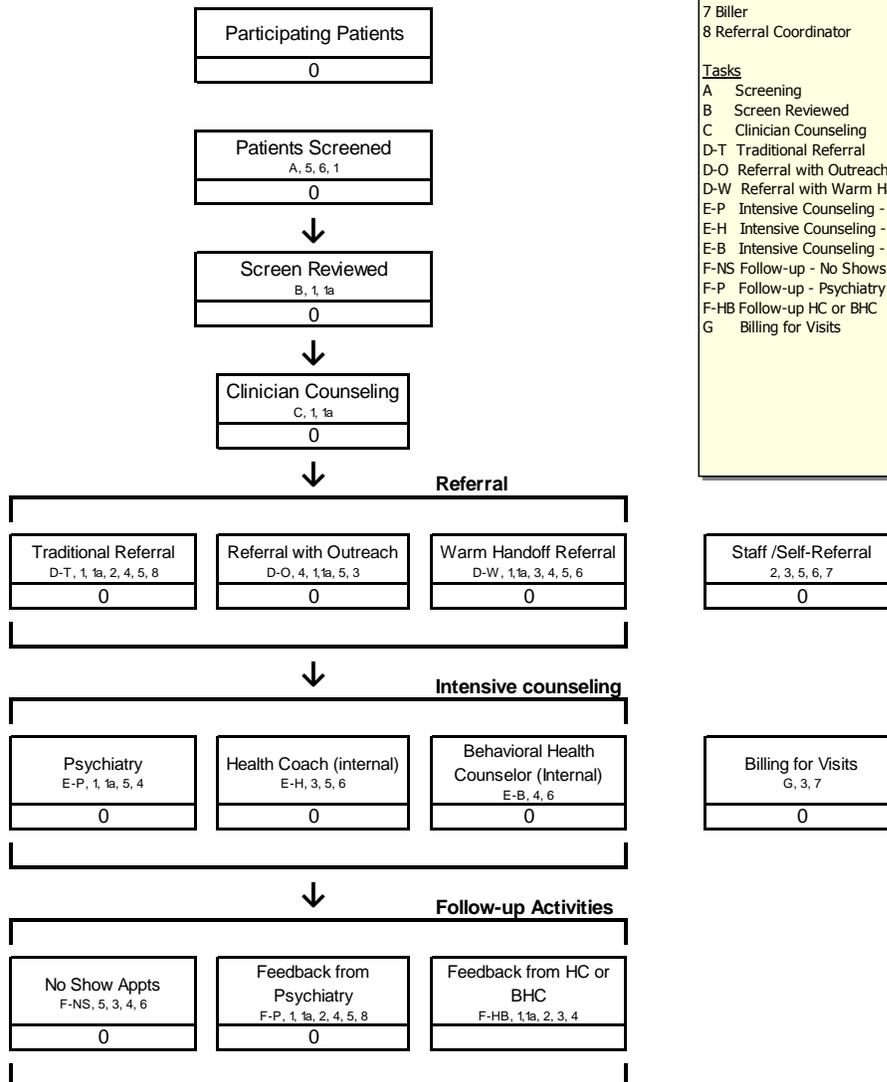

Notes (please describe the items are you including in Section B and C above. Please note if any expenditures are both start-up and developmental items):
